

DESCRIPTION

ANTI-CD40 ANTIBODY MUTANTS

Technical Field

The present invention relates to an anti-CD40 antibody which recognizes CD40 which is a type of cell membrane molecules associated with immunity. Further, the present invention relates to an antibody with a mutation in the constant region of the human antibody or with a subclass having its portion substituted in order to decrease an ADCC and/or CDC activity, while keeping an agonistic or antagonistic activity.

Background Art

1. CD40

CD40 is an antigen having a molecular weight of 50 kDa which is present on the surface of cell membrane, and expressed in B cells, dendritic cells (DCs), some types of cancer cells, and thymic epithelial cells. CD40 is known to play an important role in proliferation and differentiation of B cells and DCs. CD40 was identified as an antigen expressed on the surface of human B cells (E. A. Clark et al., Proc. Natl. Acad. Sci. USA 83: 4494, 1986; and I. Stamenkovic et al., EMBO J. 8: 1403, 1989) and has been considered as a member of the TNF receptor family which includes low-affinity NGF receptors, TNF receptors, CD27, OX40 and CD30. Ligands (CD40Ls) to human and murine CD40s have been recently cloned and found to be membrane proteins type II and expressed in activated CD4⁺T cells. CD40L has been also found to introduce strong signals for activation into human or murine B cells.

In dendritic cells, CD40 has been observed to be more highly expressed than in B cells, and it has become clear that CD40 plays an important role in dendritic cells. Binding of CD40 to CD40L activates antigen presenting cells (APCs), that is, expresses costimulator molecules such as CD80 (B7-1) and CD86 (B7-2) or enhances production of IL-2 (Caux, C., et al.: Activation of human dendritic cells through CD40 cross-linking. J. Exp. Med., 180: 1263, 1994; and Shu, U., et al.: Activated T cells induce interleukin-12 production by

monocyte via CD40 - CD40 ligand interaction. Eur. J. Immunol., 25: 1125, 1995). Dendritic cells have a strong antigen-presenting capacity and a strong capacity to activate helper T (Th) cells. Dendritic cells are also believed to control differentiation of naive Th cells into Th1 or Th2 cells. When peripheral blood monocytes, which are myeloid dendritic cells, are cultured in the presence of GM-CSF and IL-4, and matured by CD40L, the resulting matured dendritic cells (DC1) can produce IL-12 *in vitro*, and stimulate and activate allogeneic naive Th cells to induce IFN γ -producing T cells (i.e., to promote their differentiation into Th1). This action is inhibited by anti-IL-12 antibody and hence may be effected via IL-12. On the other hand, when plasmacytoid T cells, which are present in lymphoid T regions and peripheral blood, are cultured in the presence of IL-3 and CD40 ligand, the resulting lymphoid dendritic cells (DC2) are shown to be unable to produce IL-12, and stimulate and activate allogeneic naive Th cells to induce IL-4-producing T cells, which indicates promotion of their differentiation into Th2. It is believed that Th1 cells are involved in activation of cellular immunity, while Th2 cells are associated with enhancement of humoral immunity as well as restriction of cellular immunity. When cytotoxic T cells (CTL) are activated with the help of Th1 cells, they may eliminate pathogens (a number of types of virus, listeria, tuberculosis bacteria, toxoplasma protozoa, etc.) growing in the cytoplasm and tumor cells.

Monoclonal anti-CD40 antibodies, which recognize CD40 expressed on the membrane surface, have been demonstrated to have different biological activities to B cells. Monoclonal anti-CD40 antibodies are generally classified into agonistic or antagonistic antibodies against the interaction between CD40 and CD40L.

2. Agonistic Antibodies

Agonistic antibodies are known to activate B cells. For instance, the anti-CD40 antibodies are reported to induce cell adhesion (Barrett et al., J. Immunol. 146: 1722, 1991; and Gordon et al., J. Immunol. 140: 1425, 1998), increase cell size (Gordon et al., J. Immunol. 140: 1425, 1998; and Valle et al., Eur. J. Immunol. 19: 1463, 1989), induce cell division of B cells activated only by an anti-IgM antibody, anti-CD20 antibody or phorbol ester (Clark and Ledbetter, Proc. Natl. Acad. Sci. USA 83: 4494, 1986; Gordon et al., LEUCOCYTE TYPING III. A. J. McMichael ed. Oxford University Press. Oxford. p.426; and Paulie et al., J.

Immunol. 142: 590, 1989), induce cell division of B cells in the presence of IL4 (Valle et al., Eur. J. Immunol. 19: 1463, 1989; and Gordon et al., Eur. J. Immunol. 17: 1535, 1987), induce expression of IgE by cultured cells stimulated with IL-4 and deprived of T cells (Jabara et al., J. Exp. Med. 172: 1861, 1990; and Gascan et al., J. Immunol. 147: 8, 1991), induce expression of IgG and IgM by those cultured cells (Gascan et al., J. Immunol. 147: 8, 1991), secrete soluble CD23/FcεRII from cells via IL-4 (Gordon and Guy, Immunol. Today 8: 39, 1987; and Cairns et al., Eur. J. Immunol. 18: 349, 1988), enhance expression of soluble CD23/FcεRII on the cells via IL4 (Challa, A., Allergy, 54: 576, 1999), and promote IL-6 production (Clark and Shu, J. Immunol. 145: 1400, 1990). Furthermore, it is reported that addition of IL-4 and an anti-CD40 antibody to human primary culture B cells in the presence of CDw32 + adhesive cells led to establishment of cloned B cells derived therefrom (Bancherauet et al., Science 241: 70, 1991), and apoptosis of germinal center cells was inhibited through CD40 irrespective of whether its antigen receptor was active or inactive (Liu et al., Nature 342: 929, 1989). As described above, CD40 has been identified as antigen expressed on the surface of human B cells, and consequently, most of the isolated antibodies have been evaluated, as an index, mainly using their induction potency for proliferation and/or differentiation of human B cells, or their induction activity for cell death of cancer cells (Katira, A. et al., LEUKOCYTE TYPING V. S. F. Schlossossmann, et. al. eds. p.547. Oxford University Press. Oxford; W. C. Flansow et. al., LEUKOCYTE TYPING V. S. F. Schlossossmann, et. al. eds. p.555. Oxford University Press. Oxford; and J. D. Pound et. al., International Immunology, 11: 11, 1999).

The anti-CD40 antibody has been demonstrated to mature DC (Z. H. Zhou et. al., Hybridoma, 18: 471, 1999). Furthermore, the role of CD4 T cells in priming antigen-specific CD8 T cells was reported to be in activation of DC via CD40 - CD40L signaling, and the anti-CD40 monoclonal antibody (mAb) has been found to be able to replace CD40 helper T cells in activation of dendritic cells (DC) (Shoenberger, S. P., et. al.: T-cell help for cytotoxic T lymphocytes is mediated by CD40 - CD40L interactions. Nature, 480, 1998). Also, administration of an anti-CD40 antibody in mice has been found to be able to protect the animal body from CD40-expressing tumor cells as well as CD40-non-expressing tumor cells

(French, R. R., et. al.: CD40 antibody evokes a cytotoxic T-cell response that eradicates lymphoma and bypasses T-cell help. *Nature Medicine*, 5, 1999).

Agonistic anti-CD40 antibodies are expected to be effective for treatment of infectious diseases, due to bacteria, virus, etc., cancer and others, based on their functions described above. Anti-CD40 antibodies with superior agonistic activities are described in WO 02/088186. The representative examples of those agonistic antibodies are KM341-1-19 and 2105 antibodies. The hybridoma KM341-1-19 producing the KM341-1-19 antibody and the hybridoma 2105 producing the 2105 antibody were submitted on 27th, September, 2001 and 17th, April, 2002, respectively, for international deposit under the Budapest Treaty, to International Patent Organisms Depository, National Institute of Advanced Industrial Science and Technology (central 6, 1-1, Higashi 1, Tsukuba, Ibaraki, Japan). Their accession numbers are FERM BP-7759 (KM341-1-19) and FERM BP-8024 (2105).

3. Antagonistic Antibodies

Taking it in consideration, on the other hand, that CD40 plays an important role in immunologic responses, as aforementioned, it is expected that inhibition of binding of CD40 to its ligands would lead to development of therapeutic agents for immune suppression in organ transplantation and autoimmune diseases. Sawada, Hase and others have reported that the peripheral blood of patients suffering from Crohn's disease has a higher percentage of monocytes highly expressing CD40. However, such antibodies have not been well known yet as inhibit binding of CD40 to its ligands. Those inhibitory antibodies would be useful in functional analysis of CD40 and treatment of diseases requiring activation of CD40. Inhibitory antibodies to CD40 ligands are also suggested to be effective against diseases involving binding of CD40 to the CD40 ligands. However, CD40L was reported to be expressed in activated platelets (V. Henn et al., *Nature* 391: 591, 1998), and if an anti-CD40L antibody is used as a therapeutic agent, thrombus formation may occur reportedly (T. Kawai et al., *Nat. Med.* 6: 114, 2000). From this point of view, antibodies to CD40 are expected to be safer rather than anti-CD40L antibodies as therapeutic antibody agent to inhibit binding of CD40 to its ligands. Anti-CD40 antibodies would be required to inhibit binding of CD40L to CD40 and still not activate CD40 in themselves.

Such antagonistic anti-CD40 antibodies may be used for treatment of autoimmune diseases and suppression of immunologic rejections in transplantation of organs, bone marrow, etc., in view of their functions described above. Anti-CD40 antibodies with superior antagonistic activities are described in WO 02/088186. The representative example of those antagonistic antibodies is 4D11 antibody. The hybridoma 4D11 producing the 4D11 antibody was submitted on 27th, September, 2001 for international deposit under the Budapest Treaty, to International Patent Organisms Depositary, National Institute of Advanced Industrial Science and Technology (central 6, 1-1, Higashi 1, Tsukuba, Ibaraki, Japan). The accession number is FERM BP-7758.

Patent Document 1 WO 02/088186

Disclosure of the Invention

The object of the present invention is to create mutants from the potentially therapeutic anti-CD40 antibodies disclosed in WO 02/088186, which mutants are designed optimally as pharmaceutical agent.

As a result of extensive and intensive research, the present inventors have successfully created novel mutants of the agonistic or antagonistic antibodies, which mutants may have a higher therapeutic effect against diseases than known anti-CD40 antibodies, and completed the present invention based thereon. The basic idea on modification of the anti-CD40 antibodies according to the present invention will be described in detail below.

The present specification shall encompass the description in the specification and/or drawings of JP Patent Publication (Kokai) No. 2003-431408 which is the basis for the priority of the present application.

Brief Description of the Drawings

Figure 1A-1 shows binding site peptides prepared based on the CD40 sequence, to which the anti-CD40 agonistic antibodies bind;

Figure 1A-2 shows binding site peptides prepared based on the CD40 sequence, to which the anti-CD40 agonistic antibodies bind (a continuation to Figure 1A-1);

Figure 1B-1 shows binding site peptides prepared based on the CD40 sequence, to which the anti-CD40 antagonistic antibodies bind;

Figure 1B-2 shows binding site peptides prepared based on the CD40 sequence, to which the anti-CD40 antagonistic antibodies bind (a continuation to Figure 1B-1);

Figure 2A illustrates binding of the anti-CD40 antibodies to the CD40 mutant;

Figure 2B illustrates binding of the anti-CD40 antibodies to the CD40 mutant;

Figure 2C illustrates binding of the anti-CD40 antibodies to the CD40 mutant;

Figure 3A shows diagrams indicating that the KM341-1-19 antibody having a P331S mutation is as active as the original KM341-1-19 antibody with respect to binding to Ramos cells;

Figure 3B shows diagrams indicating that the KM341-1-19 antibody having a P331S mutation is as active as the original KM341-1-19 antibody with respect to enhancement of CD95 expression of Ramos cells;

Figure 4A shows a diagram indicating that the KM341-1-19 antibody having a P331S mutation has a lower CDC activity via the rabbit complement;

Figure 4B shows a diagram indicating that the G2/4 antibody has a lower complement activity when the human complement is used;

Figure 5A-1 shows diagrams indicating that conversion of the subclass of the 2105 antibody from IgG2 into different subclasses has no effect on its binding to Ramos cells;

Figure 5A-2 shows diagrams indicating that conversion of the subclass of the KM341-1-19 antibody from IgG2 into different subclasses has no effect on its binding to Ramos cells;

Figure 5B-1 shows diagrams indicating that conversion of the subclass of the 2105 antibody from IgG2 into different subclasses lowers an activity to enhance CD95 expression of Ramos cells;

Figure 5B-2 shows diagrams indicating that conversion of the subclass of the KM341-1-19 antibody from IgG2 into different subclasses lowers an activity to enhance CD95 expression of Ramos cells;

Figure 6A-1 shows diagrams indicating that the binding capacity of the KM341-1-19 antibodies to Ramos cells is independent of the varying structure of the hinge region;

Figure 6A-2 shows diagrams indicating that the binding capacity of the 2105 antibodies to Ramos cells is independent of the varying structure of the hinge region;

Figure 6B-1 shows diagrams indicating that the upper and middle hinges of the hinge region are important for the activity of the KM341-1-19 antibodies to enhance CD95 expression of Ramos cells;

Figure 6B-2 shows diagrams indicating that the upper and middle hinges of the hinge region are important for the activity of the 2105 antibodies to enhance CD95 expression of Ramos cells;

Figure 7A shows diagrams indicating that conversion of the subclass of the F72 antibody to IgG2 has no effect on its binding to Ramos cells;

Figure 7B shows diagrams indicating that conversion of the subclass of the F72 antibody to IgG2 raises an activity to enhance CD95 expression of Ramos cells;

Best Mode for Carrying Out the Invention

1. Modification of Agonistic Antibodies

Antibodies are essentially molecules that function to protect living bodies against foreign bodies, such as microorganisms and viruses, and cancer, and hence they can kill and eliminate such cells binding to themselves. The lethal activity is composed of two different activities, called Antibody-Dependent Cellular Cytotoxicity (abbreviated as ADCC hereinafter) and Complement-Dependent Cytotoxicity (abbreviated as CDC hereinafter).

ADCC refers to a type of cytotoxicity induced by activation of macrophages, NK cells, neutrophil cells, etc., which recognize target cells by binding to the constant region of the antibody via Fc receptors expressed on their surface. In contrast, CDC refers to a type of

cytotoxicity induced by activation of a complement system which occurs through binding of an antibody to an antigen. These activities are known to vary depending on a subclass of the antibody, which has been found to be due to a structural difference in the constant region of antibodies (Charles A. Janeway et al., Immunology, 1997, Current Biology Ltd./Garland Publishing Inc.).

Anti-CD40 agonistic antibodies will be more preferable as therapeutic agent if they have not the activities of ADCC and/or CDC which may induce cell death of CD40-expressing cells, in terms of mechanism of immunoactive action. If CD40-expressing cells are injured by ADCC and/or CDC activities, immunosuppression may occur rather than desired immunoactivation, resulting in exacerbation of the disease. In addition, patients suffering from infectious diseases may have higher ADCC and/or CDC activities. Therefore, when such antibodies are applied to infectious diseases, it is necessary to evaluate them for safety more carefully, for example, using more active rabbit complements than those present in healthy human serum or peripheral blood which could not be effective to detect the above activities in this situation. Accordingly, mutants and recombinants were created which had no activity of ADCC or CDC and examined for their activity.

Since ADCC and/or CDC activities are known to vary depending on a subclass of the antibody of interest, conversion of the subclass may reduce ADCC and/or CDC activities. For the human IgG subclasses, for example, IgG4 is generally known to be a subclass with low activities of both ADCC and CDC, and it is reported that IgG2 is CDC active but poorly active in ADCC, while IgG1 is highly active in both ADCC and CDC (Charles A. Janeway et al., Immunology, 1997, Current Biology Ltd./Garland Publishing Inc.). Selection of a particular subclass by taking advantage of the above characteristics may create a less cytotoxic antibody from the original antibody. A combination of a specific subclass of antibody with such a point mutation as described below may create an antibody with a desired activity. Further, reduction in ADCC and/or CDC activities of an antibody is reported to be attained by incorporation of a mutation into its constant region. For instance, L235, D265, D270, K322, P331, and P329 (each alphabetical letter denotes an amino acid by the single-letter notation, and each number denotes an EU index proposed by Kabat et al. (Kabat et. al., Sequences of

proteins of Immunological Interest, 1991 Fifth edition); such symbols will be used hereinafter.) may play an important role in complement activation by human IgG, and substitution of one of those sites by another amino acid may reduce the CDC activity. Esohe E. Idusogie et. al. *J. Immunol.* 2000, 164:4178-4184, Yuanyuan Xu et. al. *J. Biol. Chem.* 1994, 269:3469-3474, Brekke, O. H. et. al. *Eur. J. Immunol.* 1994, 24:2542, Morgan, A., et. al., *Immunology* 1995, 86:319, Lund, J., et. al.; *J. Immunol.*, 1996, 157:4963, Tao, M. H., et. al., *J. Exp. Med.* 1993, 178:661). Specifically, substitution of D270, K322, P329, or P331 by A may reduce the CDC activity. Substitution of P331 by S or G may also induce the same thing.

It is believed that Glu233-Ser239, Gly316-Lys338, Lys274-Arg301, Tyr407-Arg416, Asn297, Glu318, Leu234-Ser239, Asp265-Glu269, Asn297-Thr299 and Ala327-Ile332 take a part in binding of IgG to FcR (Duncan, A. R., Woof, J. M., Partridge, L. J., Burton, D. R., and Winter, G. (1988) *Nature* 332, 563-564, Gessner, J. E., Heiken, H., Tamm, A., and Schmidt, R. E. (1998) *Ann. Hematol.* 76, 231-248, Gavin, A., Hulett, M, and Hogarth, P. M. (1998) in *The Immunoglobulin Receptors and Their Physiological and Pathological Roles in Immunity* (van de Winkel, J. G. J. ,and Hogarth, P. M., eds), pp. 11-35, Kluwer Academic Publishers Group, Dordrecht, The Netherlands, Sautes, C. (1997) in *Cell-mediated Effects of Immunoglobulins* (Fridman, W. H., and Sautes, C., eds), pp. 29-66, R. G. Landes Co., Austin, TX, Da'ron, M. (1997) *Annu. Rev. Immunol.* 15, 203-234, Canfield, S. M., and Morrison, S. L. (1991) *J. Exp. Med.* 173, 1483-1491, Chappel, M. S., Isenman, D. E., Everett, M., Xu, Y.-Y., Dorrington, K. J., and Klein, M. H. (1991) *Proc. Natl. Acad. Sci. U.S.A.* 88, 9036-9040, Woof, J. M., Partridge, L. J., Jefferis, R., and Burton, D. R. (1986) *Mol. Immunol.* 23, 319-330, Wines, B. D., Powell, M. S., Parren, P. W. H. I., Barnes, N., and Hogarth, P. M. (2000) *J. Immunol.* 164, 5313-5318), and thus incorporation of a mutation into one of these regions may reduce the ADCC activity. Specifically, substitution of L235 by E or G237 by A can reduce binding of IgG to FcR.

The antibody according to the present invention has at least one mutation of amino acids to reduce the ADCC and/or CDC activities, preferably 1-20, 1-17, 1-16, 1-15, 1-14, 1-13, 1-12, 1-11, 1-10, 1-9, 1-8, 1-7, 1-6, 1-5, 1-4, 1-3, or 1 or 2 mutations.

The present invention has revealed that in some anti-CD40 antibodies, the hinge region of IgG2 is important in expression of their strong agonistic activities. Replacement of the variable region or the constant region except the hinge region by a counterpart of any different subclass, or incorporation of a point mutation thereinto is expected to not only modulate the ADCC and/or CDC activities, but increase the productivity of the antibody, its stability during purification and storage, and its blood kinetics.

To produce an antibody drug, the stability of the antibody during purification and storage is very important. Since the antibodies so far developed belong mainly to the IgG1 subclass, conversion of the variable region or the constant region except the hinge region to a sequence derived from the IgG1 subclass will be also effective to improve the physical properties of the anti-CD40 agonistic antibodies described above.

The present invention provides mutants of agonistic anti-CD40 antibodies and others as follows:

- [1] A heavy chain of a monoclonal antibody having an agonistic activity, which binds to CD40, wherein the heavy chain comprises an upper hinge and a middle hinge derived from a human IgG2, and a constant region with at least one amino acid deleted or substituted, or with at least one amino acid added thereto, said deletion, substitution or addition being capable of increasing or decreasing ADCC and/or CDC.
- [2] The heavy chain according to [1], wherein the constant region is derived from a human IgG.
- [3] The heavy chain according to [2], wherein the human IgG is a human IgG1.
- [4] The heavy chain according to [2], wherein the human IgG is a human IgG2.
- [5] The heavy chain according to [2], wherein the human IgG is a human IgG3.
- [6] The heavy chain according to [2], wherein the human IgG is a human IgG4.
- [7] The heavy chain according to any of [3] to [5], wherein said substitution of amino acids in the constant region is substitution of proline with serine at position 331 which is indicated by the EU index as in Kabat et al.
- [8] A monoclonal antibody comprising the heavy chain according to any of [1] to [7].

[9] The heavy chain according to any of [1] to [7], wherein the heavy chain comprises a variable region from a heavy chain of a monoclonal antibody produced by the hybridoma KM341-1-19 (Accession No. FERM BP-7759).

[10] A monoclonal antibody consisting of the heavy chain according to [9] and a light chain comprising a variable region from a light chain of a monoclonal antibody produced by the hybridoma KM341-1-19 (Accession No. FERM BP-7759).

[11] The heavy chain according to any of [1] to [7], wherein the heavy chain comprises a variable region of the polypeptide represented by SEQ ID NO: 38.

[12] A monoclonal antibody consisting of the heavy chain according to [11] and a light chain of a monoclonal antibody, wherein the light chain comprises a variable region of the polypeptide represented by SEQ ID NO: 40.

[13] The heavy chain according to [1], wherein the heavy chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 132.

[14] A monoclonal antibody consisting of the heavy chain according to [13] and a light chain of a monoclonal antibody, wherein the light chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 134.

[15] The heavy chain according to [1], wherein the heavy chain is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 131.

[16] The monoclonal antibody according to [8], wherein the monoclonal antibody is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 131 and the polynucleotide represented by SEQ ID NO: 133.

[17] The heavy chain according to any of [1] to [7], wherein the heavy chain comprises a variable region from a heavy chain of a monoclonal antibody produced by the hybridoma 2105 (Accession No. FERM BP-8024).

[18] A monoclonal antibody consisting of the heavy chain according to [17] and a light chain comprising a variable region from a light chain of a monoclonal antibody produced by the hybridoma 2105 (Accession No. FERM BP-8024).

- [19] The heavy chain according to any of [1] to [7], wherein the heavy chain comprises a variable region of the polypeptide represented by SEQ ID NO: 42.
- [20] A monoclonal antibody consisting of the heavy chain according to [19] and a light chain of a monoclonal antibody, wherein the light chain comprises a variable region of the polypeptide represented by SEQ ID NO: 44.
- [21] The heavy chain according to [1], wherein the heavy chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 136.
- [22] A monoclonal antibody consisting of the heavy chain according to [21] and a light chain of a monoclonal antibody, wherein the light chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 138.
- [23] The heavy chain according to [1], wherein the heavy chain is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 135.
- [24] The monoclonal antibody according to [8], wherein the monoclonal antibody is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 135 and the polynucleotide represented by SEQ ID NO: 137.
- [25] A polynucleotide represented by SEQ ID NO: 131.
- [26] A polynucleotide represented by SEQ ID NO: 133.
- [27] An expression vector having the polynucleotide according to [25].
- [28] An expression vector having the polynucleotide according to [26].
- [29] An expression vector having the polynucleotides according to [25] and [26].
- [30] A host comprising the expression vector according to [27].
- [31] A host comprising the expression vector according to [28].
- [32] A host comprising the expression vector according to [29].
- [33] A process of producing a heavy chain of a monoclonal antibody, comprising the steps of: culturing the host according to [30] in a culture medium; and obtaining a heavy chain of a monoclonal antibody from the culture and/or the host.

- [34] A process of producing a monoclonal antibody, comprising the steps of: culturing the host according to [32] in a culture medium; and obtaining a monoclonal antibody from the culture and/or the host.
- [35] A polynucleotide represented by SEQ ID NO: 135.
- [36] A polynucleotide represented by SEQ ID NO: 137.
- [37] An expression vector having the polynucleotide according to [35].
- [38] An expression vector having the polynucleotide according to [36].
- [39] An expression vector having the polynucleotides according to [35] and [36].
- [40] A host comprising the expression vector according to [37].
- [41] A host comprising the expression vector according to [38].
- [42] A host comprising the expression vector according to [39].
- [43] A process of producing a heavy chain of a monoclonal antibody, comprising the steps of: culturing the host according to [40] in a culture medium; and obtaining a heavy chain of a monoclonal antibody from the culture and/or the host.
- [44] A process of producing a a monoclonal antibody, comprising the steps of: culturing the host according to [42] in a culture medium; and obtaining a monoclonal antibody from the culture and/or the host.
- [45] A process of producing a heavy chain of a monoclonal antibody having an agonistic activity capable of binding to CD40, comprising the step of substituting the upper hinge and the middle hinge of an antibody, which is not either an upper hinge or a middle hinge derived from a human IgG2, with an upper hinge and a middle hinge derived from a human IgG2, respectively.
- [46] A process of producing a heavy chain of a monoclonal antibody comprising a variable region, and an upper hinge and a middle hinge derived from a human IgG2, comprising the step of identifying a polypeptide forming the variable region, which is from a heavy chain of a monoclonal antibody capable of binding to CD40.
- [47] A process of producing a monoclonal antibody having an agonistic activity capable of binding to CD40, comprising the step of substituting the upper hinge and the middle hinge of

an antibody, which is not either an upper hinge or a middle hinge derived from a human IgG2, with an upper hinge and a middle hinge derived from a human IgG2, respectively.

[48] A process of producing a monoclonal antibody comprising a variable region, and an upper hinge and a middle hinge derived from a human IgG2, comprising the step of identifying a polypeptide forming the variable region, which is from a heavy chain of a monoclonal antibody capable of binding to CD40.

[49] A pharmaceutical composition comprising the monoclonal antibody according to [8], [10], [12], [14], [16], [18], [20], [22] or [24] as an active ingredient.

[50] The pharmaceutical composition according to [49] used for prevention or treatment of a malignant tumor, a pathogen or an autoimmune disease.

[51] A method of prevention or treatment of a malignant tumor, a pathogen or an autoimmune disease, comprising administration of the pharmaceutical composition according to [49] into a mammal.

[52] Use of the monoclonal antibody according to [8], [10], [12], [14], [16], [18], [20], [22] or [24] for production of a pharmaceutical composition used for prevention or treatment of a malignant tumor, a pathogen or an autoimmune disease.

[89] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 131.

[90] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 133.

[91] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 135.

[92] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 137.

The present invention provides an antibody produced by modification of an agonistic anti-CD40 antibody belonging to the human IgG2, wherein the modified antibody is a mutant having the constant region, exclusive of the upper and middle hinges, substituted with a sequence derived from a different subclass. The subclass is preferably IgG1. The present invention provides an antibody produced by modification of an agonistic anti-CD40 antibody

belonging to the human IgG2, wherein the modified antibody is a mutant having the constant region, exclusive of the hinge region, substituted with a sequence derived from a different subclass. The subclass is preferably IgG1.

Herein, reduction in ADCC and CDC activities means reduction in those activities as compared with the corresponding activities of an anti-CD40 monoclonal antibody other than the mutants described above, for example, as compared with the corresponding activities of a monoclonal antibody produced by the hybridoma KM341-1-19 (Accession No. FERM BP-7759) or 2105 (Accession No. FERM BP-8024). The ADCC and CDC activities may be assayed by any known method, for example, the method described in the Examples herein. The sequences of variable regions in the heavy and light chains of a monoclonal antibody will be presented below which is produced by the hybridoma KM341-1-19 (Accession No. FERM BP-7759) or 2105 (Accession No. FERM BP-8024).

DNA encoding variable regions in the heavy and light chains of the KM341-1-19 antibody and the amino acid sequences of the heavy and light chains will be presented below.

In the heavy chain nucleotide sequence (SEQ ID NO: 37) of the KM341-1-19 antibody, the signal sequence is initiated with adenine (A) at position 50. The boundary between the signal sequence and the variable region is located between "adenine" ([A]) at position 109 and cytosine (C) at position 110, and the boundary between the variable region and the constant region is located between adenine (A) at position 493 and guanine (G) at position 494 (the gene prediction software (Signal P ver.2) was used).

In the heavy chain amino acid sequence (SEQ ID NO: 38) of the KM341-1-19 antibody, the boundary between the signal sequence and the variable region is located between serine (S) at position 20 and glutamine (Q) at position 21, and the boundary between the variable region and the constant region is located between serine (S) at position 148 and alanine (A) at position 149.

Accordingly, the variable region in the heavy chain of the KM341-1-19 antibody has a nucleotide sequence ranging from cytosine (C) at position 110 to adenine (A) at position 493, as seen in SEQ ID NO: 37. Further, the variable region in the heavy chain of the KM341-1-

19 antibody has an amino acid sequence ranging from glutamine (Q) at position 21 to serine (S) at position 148, as seen in SEQ ID NO: 38.

In the light chain nucleotide sequence (SEQ ID NO: 39) of the KM341-1-19 antibody, the signal sequence is initiated with adenine (A) at position 29. The boundary between the signal sequence and the variable region is located between "adenine" ([A]) at position 88 and guanine (G) at position 89, and the boundary between the variable region and the constant region is located between adenine (A) at position 400 and "cytosine" ([C]) at position 401 (the gene prediction software (Signal P ver.2) was used).

In the light chain amino acid sequence (SEQ ID NO: 40) of the KM341-1-19 antibody, the boundary between the signal sequence and the variable region is located between glycine (G) at position 20 and glutamic acid (E) at position 21, and the boundary between the variable region and the constant region is located between lysine (K) at position 124 and "arginine" ([R]) at position 125.

Accordingly, the variable region in the light chain of the KM341-1-19 antibody has a nucleotide sequence ranging from guanine (G) at position 89 to adenine (A) at position 400, as seen in SEQ ID NO: 39. Further, the variable region in the light chain of the KM341-1-19 antibody has an amino acid sequence ranging from glutamic acid (E) at position 21 to lysine (K) at position 124, as seen in SEQ ID NO: 40.

The heavy chain nucleotide sequence (SEQ ID NO: 37) of the KM341-1-19 antibody:

DNA encoding variable regions in the heavy and light chains of the 2105 antibody and the amino acid sequences of the heavy and light chains will be presented below.

In the heavy chain nucleotide sequence (SEQ ID NO: 41) of the 2105 antibody, the signal sequence is initiated with adenine (A) at position 70. The boundary between the signal sequence and the variable region is located between "thymine" ([T]) at position 126 and guanine (G) at position 127, and the boundary between the variable region and the constant region is located between adenine (A) at position 495 and guanine (G) at position 496 (the gene prediction software (Signal P ver.2) was used).

In the heavy chain amino acid sequence (SEQ ID NO: 42) of the 2105 antibody, the boundary between the signal sequence and the variable region is located between cysteine (C) at position 19 and glutamic acid (E) at position 20, and the boundary between the variable region and the constant region is located between serine (S) at position 142 and alanine (A) at position 143.

Accordingly, the variable region in the heavy chain of the 2105 antibody has a nucleotide sequence ranging from guanine (G) at position 127 to adenine (A) at position 495, as seen in SEQ ID NO: 41. Further, the variable region in the heavy chain of the 2105 antibody has an amino acid sequence ranging from glutamic acid (E) at position 20 to serine (S) at position 142, as seen in SEQ ID NO: 42.

In the light chain nucleotide sequence (SEQ ID NO: 43) of the 2105 antibody, the signal sequence is initiated with adenine (A) at position 28. The boundary between the signal sequence and the variable region is located between "adenine" ([A]) at position 87 and guanine (G) at position 88, and the boundary between the variable region and the constant region is located between adenine (A) at position 405 and "cytosine" ([C]) at position 406 (the gene prediction software (Signal P ver.2) was used).

In the light chain amino acid sequence (SEQ ID NO: 44) of the 2105 antibody, the boundary between the signal sequence and the variable region is located between glycine (G) at position 20 and glutamic acid (E) at position 21, and the boundary between the variable region and the constant region is located between lysine (K) at position 126 and "arginine" ([R]) at position 127.

Accordingly, the variable region in the light chain of the 2105 antibody has a nucleotide sequence ranging from guanine (G) at position 88 to adenine (A) at position 405, as seen in SEQ ID NO: 43. Further, the variable region in the light chain of the 2105 antibody has an amino acid sequence ranging from glutamic acid (E) at position 21 to lysine (K) at position 126, as seen in SEQ ID NO: 44.

In the heavy chain nucleotide sequence (SEQ ID NO: 131) of the 341G2Ser, the boundary between the signal sequence and the variable region is located between "adenine" ([A]) at position 60 and cytosine (C) at position 61, and the boundary between the variable region and the constant region is located between adenine (A) at position 444 and guanine (G) at position 445 (the gene prediction software (Signal P ver.2) was used).

In the heavy chain amino acid sequence (SEQ ID NO: 132) of the 341G2Ser, the boundary between the signal sequence and the variable region is located between serine (S) at position 20 and glutamine (Q) at position 21, and the boundary between the variable region and the constant region is located between serine (S) at position 148 and alanine (A) at position 149.

Accordingly, the variable region in the heavy chain of the 341G2Ser has a nucleotide sequence ranging from cytosine (C) at position 61 to adenine (A) at position 444, as seen in SEQ ID NO: 131. Further, the variable region in the heavy chain of the 341G2Ser has an amino acid sequence ranging from glutamine (Q) at position 21 to serine (S) at position 148, as seen in SEQ ID NO: 132.

In the light chain nucleotide sequence (SEQ ID NO: 137) of the 2105G2Ser, the boundary between the signal sequence and the variable region is located between "adenine" ([A]) at position 60 and guanine (G) at position 61, and the boundary between the variable region and the constant region is located between adenine (A) at position 378 and "cytosine" ([C]) at position 379 (the gene prediction software (Signal P ver.2) was used).

In the light chain amino acid sequence (SEQ ID NO: 138) of the 2105G2Ser, the boundary between the signal sequence and the variable region is located between glycine (G) at position 20 and glutamic acid (E) at position 21, and the boundary between the variable region and the constant region is located between lysine (K) at position 126 and "arginine"

([R]) at position 127. Accordingly, the variable region in the light chain of the 2105G2Ser has a nucleotide sequence ranging from guanine (G) at position 61 to adenine (A) at position 378, as seen in SEQ ID NO: 137. Further, the variable region in the light chain of the 2105G2Ser has an amino acid sequence ranging from glutamic acid (E) at position 21 to lysine (K) at position 126, as seen in SEQ ID NO: 138.

2. Modification of Antagonistic Antibodies

Anti-CD40 antagonistic antibodies will be more preferable as therapeutic agent as well as the agonistic antibodies, if they have not the activities of ADCC and/or CDC, in terms of mechanism of action. Furthermore, it is important that anti-CD40 antagonistic antibodies have no activity to induce signals by their *in vivo* crosslinking via Fc receptors, even if the ADCC activity cannot be detected. In other words, it is necessary to confirm that they are

not activate the immunity, and such active antibodies may be desired as pharmaceutical agent. Anti-CD40 antagonistic antibodies are promising as therapeutic agent for treating autoimmune diseases or suppressing rejection in organ transplantation. If they induce an agonistic activity due to some effect after they are administered to patients, however weak it may be, the symptoms may worsen in contrast to the desired therapeutic effect. Thus, an antibody without any agonistic activity is more preferable as pharmaceutical agent. In the present invention, incorporation of a point mutation L235E (means substitution of L at position 235 with E; similar symbols will be used hereinafter) into IgG4 has been demonstrated to be effective for *in vivo* reduction in the agonistic activity, in the animal test using monkeys. Although IgG4 is a subclass with low activities of ADCC and CDC, it is reported that when it was attempted to express IgG4 as recombinant protein in cells like CHO, its half-molecules were secreted due to a poor S-S bonding between the heavy chains (Rob C. Aalberse et al., Immunology, 105, 9-19, 2002). To overcome this problem, incorporation of a mutation into the constant region of antibodies is reported to successfully promote the formation of the S-S bonding. Therefore, this type of mutation was also evaluated for its usefulness. Specifically, the mutation of substituting S at position 228 with P was incorporated (S. Angal et al., Molecular Immunology, vol.30, no.1, 105-108, 1993).

For antagonistic antibodies as well as agonistic antibodies, the stability of the antibody during purification and storage is very important. There may be some methods to create such antibodies as are physically better while keeping the antagonistic activity. The antibody pharmaceuticals so far offered commercially belong mostly to the IgG1 subclass, and they are not reported to be problematic in pharmaceutical formulation. Based on these facts, it may be advantageous from the viewpoint of physical properties to derive the constant region of antibodies from IgG1. In case of anti-CD40 antibodies, however, they are desirably lower in ADCC and CDC activities. As a consequence, antibodies having an IgG1-type constant region modified with some point mutations may be desired. The mutations described above are useful to create such antibodies. The IgG1-type constant region may become lower in ADCC and CDC activities by incorporating point mutation P331G therein. It is also observed that incorporation of point mutation L235E into IgG4 eliminates a slight agonistic

activity *in vivo* to make it pharmaceutically more active, but makes it physically less stable at a low pH. Thus, substitution of L235 with an amino acid other than E may make it physically more functional. As to the 4D11 antibody, it is very similar to the 2B11 antibody with respect to the structure of its variable region. The 2B11 antibody has a lower antagonistic activity, but has a higher stability at a low pH, compared with the 4D11 antibody. If some amino acids derived from the constant region of 2B11 are incorporated into the 4D11 antibody, based on the above properties, 4D11 may become more stable. Specifically, point mutation L38V, P58R, G62W, I79M, K81Y, H87Y, S98A, K109R, V120M or T124A in the heavy chain, or N75S in the light chain, or a combination thereof may be effective for that purpose. Specifically, a mutant created by substituting L at position 38 in the variable region of the heavy chain of the 4D11 antibody with V (abbreviated as L38V; similar symbols will be used hereinafter), a P58R mutant, a G62W mutant, a I79M mutant, a K81Y mutant, a H87Y mutant, a S98A mutant, a K109R mutant, a V120M mutant or a T124A mutant, or a N75S mutant in the light chain, or a combination thereof may be provided for that purpose.

The antibody according to the present invention has at least one mutation of amino acids to reduce the ADCC and/or CDC activities, preferably 1-15, 1-13, 1-12, 1-11, 1-10, 1-9, 1-8, 1-7, 1-6, 1-5, 1-4, 1-3, or 1 or 2 mutations.

The present invention provides mutants of antagonistic anti-CD40 antibodies and others as follows:

[53] A heavy chain of a monoclonal antibody having an antagonistic activity capable of binding to CD40, wherein the heavy chain comprises a constant region with at least one amino acid deleted or substituted, or with at least one amino acid added thereto, said deletion, substitution or addition being capable of increasing or decreasing ADCC and/or CDC.

[54] The heavy chain according to [53], wherein the constant region is derived from a human IgG.

[55] The heavy chain according to [54], wherein the human IgG is a human IgG1.

[56] The heavy chain according to [54], wherein the human IgG is a human IgG2.

[57] The heavy chain according to [54], wherein the human IgG is a human IgG3.

[58] The heavy chain according to [54], wherein the human IgG is a human IgG4.

[59] The heavy chain according to any of [55], [57] or [58], wherein said substitution of amino acids in the constant region is substitution of leucine with glutamic acid at position 235 which is indicated by the EU index as in Kabat et al.

[60] A heavy chain according to any of [53] to [58], wherein the heavy chain comprises a constant region with at least one amino acid deleted or substituted, or with at least one amino acid added thereto, said deletion, substitution or addition being capable of promoting the formation of the S-S bond between the heavy chains.

[61] The antibody heavy chain according to [60], wherein said substitution of amino acids in the constant region is substitution of serine with proline at position 228 which is indicated by the EU index as in Kabat et al.

[62] A monoclonal antibody comprising the heavy chain according to any of [53] to [61].

[63] The heavy chain according to any of [53] to [61], wherein the heavy chain comprises a variable region from a heavy chain of a monoclonal antibody produced by the hybridoma 4D11 (Accession No. FERM BP-7758).

[64] A monoclonal antibody comprising the heavy chain according to [63] and a light chain comprising a variable region from a light chain of a monoclonal antibody produced by the hybridoma 4D11 (Accession No. FERM BP-7758).

[65] The heavy chain according to any of [53] to [61], wherein the heavy chain comprises a variable region of the polypeptide represented by SEQ ID NO: 46.

[66] A monoclonal antibody consisting of the heavy chain according to [65] and a light chain of a monoclonal antibody, wherein the light chain comprises a variable region of the polypeptide represented by SEQ ID NO: 48.

[67] The heavy chain according to [53], wherein the heavy chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 140.

[68] A monoclonal antibody consisting of the heavy chain according to [67] and a light chain of a monoclonal antibody, wherein the light chain consists of a remaining portion provided by removing the signal sequence from the polypeptide represented by SEQ ID NO: 142.

- [69] The heavy chain according to [53], wherein the heavy chain is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 139.
- [70] The monoclonal antibody according to [62], wherein the monoclonal antibody is produced by a host comprising an expression vector having the polynucleotide represented by SEQ ID NO: 139 and the polynucleotide represented by SEQ ID NO: 141.
- [71] A polynucleotide represented by SEQ ID NO: 139.
- [72] A polynucleotide represented by SEQ ID NO: 141.
- [73] An expression vector having the polynucleotide according to [71].
- [74] An expression vector having the polynucleotide according to [72].
- [75] An expression vector having the polynucleotides according to [71] and [72].
- [76] A host comprising the expression vector according to [73].
- [77] A host comprising the expression vector according to [74].
- [78] A host comprising the expression vector according to [75].
- [79] A process of producing a heavy chain of a monoclonal antibody, comprising the steps of: culturing the host according to [76] in a culture medium; and obtaining a heavy chain of a monoclonal antibody from the culture and/or the host.
- [80] A process of producing a monoclonal antibody, comprising the steps of: culturing the host according to [78] in a culture medium; and obtaining a monoclonal antibody from the culture and/or the host.
- [81] A pharmaceutical composition comprising the monoclonal antibody according to [62], [64], [66], [68] or [70] as an active ingredient.
- [82] The pharmaceutical composition according to [81] used for prevention or treatment of transplant rejection, an autoimmune disease, allergy or blood clotting factor VIII inhibition.
- [83] A method of prevention or treatment of transplant rejection, an autoimmune disease, allergy or blood clotting factor VIII inhibition, which comprises administering the pharmaceutical composition according to [81] into a mammal.
- [84] Use of the monoclonal antibody according to [62], [64], [66], [68] or [70] for production of a pharmaceutical composition used for prevention or treatment of transplant rejection, an autoimmune disease, allergy or blood clotting factor VIII inhibition.

[85] A method of producing a heavy chain of a monoclonal antibody having an antagonistic activity capable of binding to CD40, wherein the agonistic activity is lowered, comprising a step of making deletion or substitution of at least one amino acid, or addition of at least one amino acid in a constant region of a heavy chain of a human antibody.

[86] The method according to [85], wherein the constant region is from a human IgG.

[87] The method according to [86], wherein the human IgG is a human IgG4.

[88] The method according to any of [85] to [87], wherein said substitution of amino acids in the constant region is substitution of leucine with glutamic acid at position 235 which is indicated by the EU index as in Kabat et al.

[93] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 139.

[94] A polynucleotide provided by removing the portion encoding the signal sequence from the polynucleotide represented by SEQ ID NO: 141.

Additionally, the present invention provides the materials below.

A mutant of an antagonistic anti-CD40 antibody, comprising at least one substitution selected from the group consisting of substitution of L with V at position 38, substitution of P with R at position 58, substitution of G with W at position 62, substitution of I with M at position 79, substitution of K with Y at position 81, substitution of H with Y at position 87, substitution of S with A at position 98, substitution of K with R at position 109, substitution of V with M at position 120 and substitution of T with A at position 124, which substitutions are all carried out in a variable region of a heavy chain of a monoclonal antibody produced by the hybridoma 4D11 (Accession No. FERM BP-7758), and a mutant of an antagonistic anti-CD40 antibody comprising substitution of N with S at position 75 in a variable region of a light chain of the 4D11 antibody.

Herein, reduction in ADCC and CDC activities means reduction in those activities as compared with the corresponding activities of an anti-CD40 monoclonal antibody other than the mutants described above, for example, as compared with the corresponding activities of a monoclonal antibody produced by the hybridoma 4D11 (Accession No. FERM BP-7758). The ADCC and CDC activities may be assayed by any known method, for example, the

method described in the Examples herein. The sequences of variable regions in the heavy and light chains of a monoclonal antibody will be presented below which is produced by the hybridoma 4D11 (Accession No. FERM BP-7758).

DNA encoding variable regions in the heavy and light chains of the 4D11 antibody and the amino acid sequences of the heavy and light chains will be presented below, respectively.

In the heavy chain nucleotide sequence (SEQ ID NO: 45) of the 4D11 antibody, the boundary between the signal sequence and the variable region is located between "cytosine" ([C]) at position 93 and cytosine (C) at position 94, and the boundary between the variable region and the constant region is located between adenine (A) at position 456 and guanine (G) at position 457 (the gene prediction software (Signal P ver.2) was used).

In the heavy chain amino acid sequence (SEQ ID NO: 46) of the 4D11 antibody, the boundary between the signal sequence and the variable region is located between serine (S) at position 26 and glutamine (Q) at position 27, and the boundary between the variable region and the constant region is located between serine (S) at position 147 and alanine (A) at position 148.

Accordingly, the variable region in the heavy chain of the 4D11 antibody has a nucleotide sequence ranging from cytosine (C) at position 94 to adenine (A) at position 456, as seen in SEQ ID NO: 45. Further, the variable region in the heavy chain of the 4D11 antibody has an amino acid sequence ranging from glutamine (Q) at position 27 to serine (S) at position 147, as seen in SEQ ID NO: 46.

In the light chain nucleotide sequence (SEQ ID NO: 47) of the 4D11 antibody, the boundary between the signal sequence and the variable region is located between "thymine" ([T]) at position 124 and guanine (G) at position 125, and the boundary between the variable region and the constant region is located between adenine (A) at position 442 and "cytosine" ([C]) at position 443 (the gene prediction software (Signal P ver.2) was used).

In the light chain amino acid sequence (SEQ ID NO: 48) of the 4D11 antibody, the boundary between the signal sequence and the variable region is located between cytosine (C) at position 22 and alanine (A) at position 23, and the boundary between the variable region

and the constant region is located between lysine (K) at position 128 and "arginine" ([R]) at position 129.

Accordingly, the variable region in the light chain of the 4D11 antibody has a nucleotide sequence ranging from guanine (G) at position 125 to adenine (A) at position 442, as seen in SEQ ID NO: 47. Further, the variable region in the light chain of the 4D11 antibody has an amino acid sequence ranging from alanine (A) at position 23 to lysine (K) at position 128, as seen in SEQ ID NO: 48.

3. Definition

The terms used herein will be defined below.

"CD40" described in the present invention refers to a polypeptide having the amino acid sequence described in E. A. Clark et al., Proc. Natl. Acad. Sci. USA 83: 4494, 1986, or I. Stamenkovic et al., EMBO J. 8: 1403, 1989, and particularly, an antigenic polypeptide expressed on the surface of B cells, DC, macrophages, endothelial cells, epithelial cells or tumor cells derived from them.

"An anti-CD40 antibody" refers to any monoclonal antibody to a cell-expressed CD40, a full-length CD40 or a partial-length CD40.

In addition, "an antibody" of the invention is derived from genes (collectively called antibody genes) encoding a heavy chain variable region and a heavy chain constant region, as well as a light chain variable region and a light chain constant region which together constitute an immunoglobulin. Human immunoglobulins are grouped into 5 different classes consisting of IgG, IgA, IgM, IgD, and IgE. Further, IgG is composed of 4 different subclasses, IgG1, IgG2, IgG3 and IgG4, while IgA is composed of 2 different subclasses, IgA1 and IgA2. IgG1, IgG2, IgG3 and IgG4 are located in 14q32, 33 of the human chromosomes. The fundamental structure of immunoglobulin is composed of two homologous L chains (light chains) and two homologous H chains (heavy chains). The class and subclass of an immunoglobulin is determined by its H chains. The antibody according to the present invention may comprise any class, any subclass or any isotype of immunoglobulin. "A functional fragment" of the inventive antibody refers to a portion (partial fragment) of the antibody defined above that is active singly or multiply on an antigen to the antibody, including, for example, F(ab')₂, Fab', Fab, Fv, disulfide-stabilized FV, single-chain FV (scFV) and a multimer thereof (D. J. King, Applications and Engineering of Monoclonal Antibodies, 1998, T. J. International Ltd.).

Up to now, it has been known that IgG1 includes J00228, Z17370 and Y14737, IgG2 includes J00230, AJ250170, AF449616, AF449617, AF449618, Z49802 and Z49801, IgG3 includes M12958, K01313, X16110, X99549, AJ390236, AJ390237, AJ390238, AJ390241, AJ390242, AJ390246, AJ390247, AJ390252, AJ390244, AJ390254, AJ390260, AJ390262,

AJ390272, AJ390276 and AJ390279, and IgG4 includes K01316, AJ001563 and AJ001564 (the symbols listed above indicates accession numbers of the genes).

In the present invention, CH1, hinge, CH2 and CH3 each denote a portion of the heavy-chain constant region of any antibody, and are based on the EU index as in Kabat et al. (Kabat et al., Sequences of proteins of immunological interest, 1991 Fifth edition). By definition, CH1 ranges from 118 to 215 by the EU index, hinge ranges from 216 to 230 by the EU index, CH2 ranges from 231 to 340 by the EU index, and CH3 ranges from 341 to 446 by the EU index.

The "human antibody" of the present invention means an antibody which is an expression product of a human-derived antibody gene.

"Agonistic" refers to an action of enhancing binding of a ligand to CD40 expressed on the surface of such cells as B cells, tumor cells or dendritic cells, or an action of providing the CD40-expressing cells with at least one effect which the CD40 ligand makes on the CD40-expressing cells. "An agonistic antibody" refers to an antibody having such an agonistic action. An example of the effects provided for the CD40-expressing cells is to promote the expression of CD95.

"Antagonistic" refers to an action of inhibiting binding of the ligand to CD40 expressed on the surface of such cells as B cells, tumor cells or dendritic cells, or an action of neutralizing at least one effect which the CD40 ligand makes on the CD40-expressing cells. "An antagonistic antibody" refers to an antibody having such an antagonistic action. An example of the effects provided for the CD40-expressing cells is to suppress the proliferation of B cells or the production of antibodies.

The present application clearly presents antibodies, or heavy chain or light chain variable regions thereof by amino acid sequences. The present invention also encompasses the amino acid sequences with at least one amino acid deleted or substituted, or added thereto, preferably 1-10, 1-9, 1-8, 1-7, 1-6, 1-5, 1-4, 1-3, or 1 or 2 amino acids.

The present application clearly presents genes which encode antibodies, or heavy chain or light chain variable regions thereof by nucleotide sequences. The present invention also

encompasses the nucleotide sequences with at least one nucleotide deleted or substituted, or added thereto, preferably 1-10, 1-9, 1-8, 1-7, 1-6, 1-5, 1-4, 1-3, or 1 or 2 amino acids.

The anti-CD40 antibody according to the present invention can be provided by incorporating an antibody gene into an expression vector, transfecting the vector into a suitable host cell, harvesting the antibody from the cultured cells or the supernatant, and purifying it.

The vector may be a phage or a plasmid which can replicate in the host cell by itself or can be integrated into the chromosome of the host cell. The plasmid DNA may be derived from *Escherichia coli*, *Bacillus subtilis* or a yeast, while the phage DNA may be from λ phage.

The host cell for transformation is not particularly limited if it can express the target gene. Examples of the host cell may include bacteria (*Escherichia coli*, *Bacillus subtilis*, etc.), yeasts, animal cells (COS cell, CHO cell, etc.) and insect cells.

There are known modes of transferring the gene into the host cells, including any mode, such as mediation by calcium ion, electroporation, spheroplast fusion, mediation by lithium acetate, calcium phosphate transfection or lipofection. In order to transfer the gene into an animal, as described later, the modes include microinjection; electroporation or lipofection for ES cells; and nuclear transplantation.

In the present invention, "culture" refers to (a) culture supernatant, (b) cultured cells, cultured biomass or disrupted matter thereof, or (c) secretion of transformant. To culture the transformant, a medium suitable for the host is used and static culture, roller bottle culture or something else may be employed.

After the culture, if the desired antibody protein is produced within the biomass or cells, the antibody is harvested by disrupting the biomass or cells. If the desired antibody is produced out of the biomass or cells, the culture solution is used as it is or after it is separated from the biomass or cells by centrifugation or other means. Thereafter, a biochemical process utilizing any chromatography, which is appropriate for separation/purification of proteins, is employed alone or optionally in combination with another to separate/isolate the desired antibody from the culture.

Furthermore, the technology of creating a transgenic animal may be used to produce a transgenic animal that is a host animal having the gene integrated into an endogenous gene,

such as a transgenic bovine, a transgenic goat, a transgenic sheep or a transgenic pig (Wright, G., et al., (1991) Bio/Technology 9, 830-834) and a large amount of a monoclonal antibody derived from the antibody gene can be obtained from the milk secreted from the transgenic animal.. The culture of a hybridoma *in vitro* can be done by using a known nutrient medium or any nutrient medium derivatively prepared from known basic media as used to grow, maintain and store the hybridoma and to produce a monoclonal antibody in the supernatant, depending on the properties of the cultured hybridoma, the purpose of the study and the culture method.

4. Antibody Properties

(1) Agonistic Antibodies

The mutant of the agonistic antibody according to the present invention may activate the immune system without injuring immunocompetent cells, since it has an ADCC and/or CDC activity equal to or lower than the original antibody, while keeping an agonistic activity. It is thus expected that the mutant exhibits the immunoactivating action which is equal to or higher than the original antibody and the cytotoxicity to CD40-expressing cells which is equal to or lower than the original antibody.

(2) Antagonistic Antibodies

The mutant of the antagonistic anti-CD40 antibody according to the present invention has the reduced ADCC and/or CDC activity compared to the unmodified antibody, while keeping a suppressive activity against immunoactivating signals induced by CD40L. It is also expected to decrease the activity of signal induction *in vivo* which is considered to occur via Fc receptors.

5. Pharmaceutical Compositions

A pharmaceutical composition containing a formulation of the purified antibody according to the present invention is also within the scope of the present invention. The pharmaceutical composition may preferably contain a physiologically acceptable diluent or carrier in addition to the antibody, and may be a mixture thereof with a different antibody or a different drug such as an antibiotic agent. The suitable carrier may include, but not limited to, physiological saline, phosphate buffered physiological saline, phosphate buffered

physiological saline glucose solution and buffered physiological saline. Alternatively, the antibody may be freeze-dried for storage and when it is used, reconstituted in an aqueous buffer as described above. The pharmaceutical composition may be administered via the oral route, or the parenteral route, such as intravenous, intramuscular, subcutaneous or intraperitoneal injection or dosing.

A single effective dose, which is a combination of the antibody of the present antibody with a suitable diluent and a physiologically acceptable carrier, is from 0.0001 mg to 100 mg per kg of body weight, and it may be taken at a time interval of from 2 days to 8 weeks.

When the pharmaceutical composition of the present antibody is an agonistic antibody, it is used as: immunostimulant (antiviral or anti-infective agent) for pathogens including, for example, hepatitis A, B, C, D or E virus, HIV, influenza virus, simple herpes virus, cytomegalovirus, EB virus, papiloma virus, chlamydia, mycoplasma, toxoplasma, malaria, trypanosome and tubercle bacillus; antitumor agent for malignant tumors having cancer cells with CD40 expressed, including, for example, pancreatic cancer, bladder cancer, lymphoma (e.g., Hodgkin's lymphoma), leukemia, malignant melanoma, pancreatic cancer, lung cancer, ovarian cancer, bladder cancer, breast cancer, colon cancer, prostatic cancer, and head and neck cancer; and therapeutic agent for autoimmune diseases such as rheumatism. The pharmaceutical composition may be used for a combination of the above diseases. It may be also used in combination as adjuvant for a cancer-specific peptide. When the pharmaceutical composition is an antagonistic antibody, on the other hand, it is useful as: immunosuppressant in organ transplantation (preventive or therapeutic agent for rejection in transplantation of pancreatic islets, kidney or something else, or GVHD), therapeutic agent for autoimmune diseases (e.g., rheumatism, psoriasis, chronic ulcerative colitis, Crohn's disease, systemic lupus erythematosus, multiple sclerosis, myasthenia, scleroderma, antiphospholipid antibodies syndrome, autoimmune hepatitis, idiopathic thrombocytopenic purpura, Behcet's syndrome, arteriosclerosis, nephritis and respiratory distress syndrome), therapeutic agent for allergy (e.g., asthma), and therapeutic agent for blood clotting factor VIII inhibition. The pharmaceutical composition may be used for a combination of the above diseases.

6. Epitopes

The binding epitopes of CD40 were determined for the KM341-1-19 and 2105 antibodies having a superior agonistic activity, and for the 4D11 antibody having a superior antagonistic activity, respectively (Example 2). The present invention provides antibodies having an agonistic or antagonistic activity which have a different variable region sequence from those of the above antibodies but recognize the same epitope as one of the above antibodies. These antibodies can be obtained in such a procedure as described below.

When it is intended to acquire an agonistic anti-CD40 antibody recognizing the same epitope as the KM341-1-19 antibody, for example, mice or the likes are immunized with CD40 to provide monoclonal antibodies, from which some monoclonal antibodies competing with the KM341-1-19 antibody to bind to CD40 are screened according to the standard procedure. From the screened antibodies, an antibody having the same pattern of binding to the peptide as the KM341-1-19 antibody is selected according to the method described in Example 2.

The present invention will be described in more detail below with reference to examples. However, the present invention is not limited to embodiments described in the examples.

Example 1: Expression and purification of antibody and antigen proteins

A vector plasmid containing a variable region of an antibody was transfected into CHO cells (ATCC), and antibody-expressing cells were selected by G418 to prepare a stable expression cell line.

A mutant antigen was expressed by transiently introducing a vector into HEK cells (ATCC).

An anti-CD40 antibody was purified from the above culture supernatant by the following method. The culture supernatant containing an anti-CD40 antibody was affinity purified in a Hyper D Protein A column (manufactured by NGK Insulators, Ltd.) or in case of mouse IgG1 purification, a Protein G column (Amersham Pharmacia Biotech) according to the attached instruction using PBS(-) as an adsorption buffer and a 0.1 M sodium citrate buffer (pH 3) as an elution buffer. The eluted fraction was adjusted to about pH 7.2 by addition of a 1 M Tris-HCl (pH 8.0) or Na₂HPO₄ solution. The prepared antibody solution was substituted

with PBS(-) using a dialysis membrane (10,000 cuts, manufactured by Spectrum Laboratories, Inc.) or an SP column (Amersham Pharmacia Biotech), and filtered and sterilized using a membrane filter MILLEX-GV with a pore diameter of 0.22 μm (manufactured by Millipore Corp.). The concentration of the purified antibody was calculated by measurement of the absorbance at 280 nm, taking 1 mg/ml as 1.450D.

Example 2: Determination of epitopes

A 13-mer peptide covering amino acid 175 (SEQ ID NO: 1) in an extracellular region of CD40 was shifted by two amino acids each to synthesize 82 peptides in total (SEQ ID NOS: 49 to 130) as spots from the C-terminal on a cellulose membrane and acetylate the N-terminal thereof (Jerini AG, Germany). The reaction thereafter was carried out based on a conventional Western analysis (see Reineke, U. et al. (2001), "Epitope mapping with synthetic peptides prepared by SPOT synthesis." Antibody Engineering (Springer Lab Manual) Eds.: Kontermann/Dubel, 433-459, for example). In the analysis, coloring intensity of each spot was quantified using LumiImagerTM (Boehringer-Mannheim Corp.) (Figures 1A-1, A-2, B-1 and B-2).

The results confirmed that an 4D11 antibody strongly recognizes the 20th to 24th and 41st peptides, a 2105 antibody strongly recognizes the 12th to 23rd and 64th peptides, a KM341-1-19 antibody strongly recognizes the 41st and 42nd peptides, KM643-4-11 strongly recognizes the 43rd peptide, F72 strongly recognizes the 75th peptide, 110 strongly recognizes the 64th peptide, F4-465 strongly recognizes the 34th, 35th, 54th, 55th, 65th, 66th and 75 peptides, KM281-1-10 strongly recognizes the 21st, 24th, 64th and 75th peptides, 2B11 (novel antibody) strongly recognizes the 21st, 24th and 64th peptides, and F76 (novel antibody) strongly recognizes the 21st, 35th, 51st and 52nd peptides.

In order to confirm the binding site of the anti-CD40 antibody, a CD40-FC fusion protein having a mutation introduced therein was prepared, and the binding ability thereto was examined by ELISA. Since the anti-CD40 antibody does not cross-react with mouse B cells, five CD40Fc fusion proteins were prepared by partially converting the amino acid sequence into that of mouse CD40. Binding of the antibody to the antigens was examined.

The method for preparing the mutant CD40-FC fusion proteins is shown below. The mutation site was prepared by introducing a mouse CD40 sequence into a part to which the antibody strongly binds of the peptide sequence. CD40mut1 converted EFTE at a site corresponding to the 15th peptide into ALEK, CD40mut2 converted LDT at a site corresponding to the 21st peptide into SAQ, CD40mut3 converted TH at a site corresponding to the 24th peptide into IR, CD40mut4 converted EEGW at a site corresponding to the 42nd peptide into KEGQ, and CD40mut5 converted VSSA at a site corresponding to the 64th peptide into QSSL. The mutants were prepared according to a gene engineering technique (Figures 2A, B and C). The analysis results confirmed that the 2105 antibody has extremely reduced binding ability to CD40mut1. The results also confirmed that the 4D11 antibody and 2B11 have reduced binding ability to CD40mut2.

Example 3: Binding activity of anti-CD40 agonistic antibody to Ramos cells

A Ramos cell line was suspended in a PBS staining buffer (SB) containing 0.1% NaN₃ and 2% FCS at a concentration of 2×10^6 /ml. The cell suspension (100 μ l/well) was dispensed to a 96-well round-bottom plate (manufactured by Becton, Dickinson and Company). Each hybridoma culture supernatant (50 μ l) was added, and incubated at an ice temperature for 30 minutes. A human IgG1 antibody to human serum albumin as a negative control was adjusted to a concentration of 2 μ g/ml in a hybridoma culture medium, added in an amount of 50 μ l, and then incubated at an ice temperature for 15 minutes. After washing the plate with SB, 50 μ l of a 250-fold diluted R-PE fluorescently labeled anti-human antibody (manufactured by Southern Biotechnology Associates, Inc.) was added, and incubated at an ice temperature for 15 minutes. After washing the plate with SB twice, it was suspended in 300 to 500 μ l of a FACS buffer, and fluorescence intensity of each cell was measured using FACS (FACSort, FACScan, manufactured by Becton, Dickinson and Company).

Example 4: Evaluation of agonistic activity of anti-CD40 agonistic antibody to Ramos cells

5.0×10^5 cells/ml of a Ramos cell suspension was seeded on a 96-well plate at 100 μ l/well. A hybridoma culture supernatant or purified antibody was diluted to 20 μ g/ml in a

medium, and the dilution was added to the 96-well plate at a concentration of 100 μ l/well. After culturing overnight, cells were harvested, and R-PE labeled anti-CD95 antibody (Pharmingen NJ) was used for the cells. Analysis was carried out using FACScan or FACSsort (Becton, Dickinson and Company).

Example 5: Inhibition of CD95 expression by anti-CD40 antagonistic antibody in Ramos cells

1.0×10^6 cells/ml of a Ramos cell suspension was seeded on a 96-well plate at 50 μ l/well. A hybridoma culture supernatant or purified antibody was adjusted to 2 μ g/ml in a medium, and the medium was added to the 96-well plate at 100 μ l/well. 4 μ g/ml of a soluble CD40 ligand (Alexis Corporation) and 4 μ g/ml of an anti-FLAG antibody (M2, Sigma) were added to a medium, and the medium was added to a 96-well plate at 50 μ l/well. After culturing overnight, cells were harvested, and an R-PE labeled anti-CD95 antibody (Pharmingen NJ) was used for the cells. Analysis was carried out using FACS.

Example 6: Measurement of CDC activity in anti-CD40 antibody

In the CDC assay, 2,000 Cr^{51} -labeled target cells and a human serum-derived complement (manufactured by Sigma Co.) or rabbit serum-derived complement (Cedarlane Laboratories Limited, Ontario, Canada) at a final concentration of 5% were cultured in a round-bottom 96-well plate in a total volume of 200 μ L together with the antibody at various concentrations at 37°C in the presence of 5% CO_2 for two hours.

After culturing, the plate was centrifuged to cause the cells to precipitate, and then 50 μ L of the supernatant was transferred to a 96-well plate including a powder scintillator (LumaplateTM-96: manufactured by Packard Instrument Co., Inc.) and dried at 55°C for 1.5 hours. After confirming that the plate was dried, it was covered with a special cover (TopSealTM-A: 96-well microplates: manufactured by Packard Instrument Co., Inc.), and the γ -ray dose was measured with a scintillation counter (TopCount: manufactured by Packard Instrument Co., Inc.).

Example 7: Measurement of ADCC activity of anti-CD40 antibody

As antibody-mediated cytotoxicity, cytotoxicity to target cells in the presence of cells having killer activity such as NK cells or neutrophils and an antibody (Antibody-Dependent Cellular Cytotoxicity, hereinafter ADCC), and cytotoxicity to target cells in the presence of a complement and an antibody (Complement-Dependent Cytotoxicity, hereinafter CDC) were measured. hIgG was used as a control.

The measurement method is simply described as follows. Radioactive chromium (Cr^{51}) was incorporated into the cytoplasm of the target cells, and the amount of Cr^{51} released in the culture solution by cell death was measured as a γ -ray dose.

Specifically, 10^5 target cells of a Burkitt's lymphoma cell line Raji (ATCC CCL-86) were suspended in 15 μL of fetal calf serum (FCS). 50 μL (37 MBq/mL) of Cr^{51} -labeled sodium chromate (manufactured by PerkinElmer, Inc.: hereinafter referred to as Cr^{51}) was added to the suspension, and the cells were cultured at 37°C for one hour. Next, 10 mL of a medium was added, and the medium was discarded by centrifugation. This operation was repeated three times to remove Cr^{51} not incorporated in the cells.

In the ADCC assay, 2,000 Cr^{51} -labeled target cells and 200,000 healthy human peripheral blood mononuclear leukocytes obtained by the method described in Example 6 were cultured in a round-bottom 96-well plate (manufactured by Falcon) in a total volume of 200 μL together with the antibody at various concentrations at 37°C in the presence of 5% CO_2 for four hours.

After culturing, the plate was centrifuged to cause the cells to precipitate, and then 50 μL of the supernatant was transferred to a 96-well plate including a powder scintillator (LumaplateTM-96: manufactured by Packard Instrument Co., Inc.) and dried at 55°C for 1.5 hours. After confirming that the plate was dried, the plate was covered with a special cover (TopSealTM-A: 96-well microplates: manufactured by Packard Instrument Co., Inc.), and the γ -ray dose was measured with a scintillation counter (TopCount: manufactured by Packard Instrument Co., Inc.).

Example 8: Preparation and activity evaluation of anti-CD40 agonistic antibody P331S mutant

Gene cloning of anti-CD40 agonistic antibodies KM341-1-19 and 2105 is described in WO 02/099186. It is reported that CDC activity is reduced by converting Pro at position 331 in the IgG2 constant region into Ser. To reduce CDC activity of the KM341-1-19 antibody and the 2105 antibody, a P331S mutation was introduced into the IgG2 constant region thereof.

The human IgG1 constant region of an antibody-expressing vector N5KG1-Val Lark (IDEC Pharmaceuticals: hereinafter abbreviated to N5KG1) was substituted with human IgG2 to prepare N5KG2, and the Pro at position 331 of IgG2 was converted into Ser to prepare a mutation. cDNA cloning of the IgG2 constant region was carried out by harvesting KM341-1-19 hybridoma by centrifugation, adding TRIZOL (Gibco BRL), and extracting total RNA according to the instruction. The antibody cDNA variable region was cloned using a SMART RACE cDNA amplification kit of Clontech Laboratories, Inc. according to the attached instruction. 1st strand cDNA was prepared using 5 µg of total RNA as a template. PCR was carried out with tnIgG3Nhe: atatGCTAGCACCAAGGGCCCATCGGTCTTCCCCCTGGC (SEQ ID NO: 2)G and tnIgG2Bam: atatggatccTCATTTACCCGGAGACAGGGAGAGGCTC (SEQ ID: 3) as primer sequences using a ZtaqPCR kit (Takara) in 30 cycles each consisting of reaction at 98°C for 1 second, at 55°C for 30 seconds and at 72°C for 1 minute to amplify the gene. After the reaction, the amplified product was purified by a QIAGEN PCR purification kit, digested with NheI and BamHI, and incorporated into N5KG1 to confirm the sequence. This vector was defined as N5KG2.

N5KG2Ser (with Pro at position 331 converted into Ser) was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers IgG3Nhe: atatGCTAGCACCAAGGGCCCATCGGTCTTCCCCCTGGCG (SEQ ID NO: 4) and G2Ser2: GTTTTCTCGATGGAGGCTGGGAGGCC (SEQ ID NO: 5). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers IgG2Bam: atatggatccTCATTTACCCGGAGACAGGGAGAGGCTC (SEQ ID NO: 6) and G2Ser1: GGCCTCCCAGCCTCCATCGAGAAAAC (SEQ ID NO: 7). The amplified DNA

fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers IgG3Nhe and IgG2Bam were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector (N5KG2Ser). The fragment containing the sequence of the antibody variable region digested with BglII and NheI was incorporated into the N5KG2Ser vector.

The antibody expressed and purified by the above method was evaluated in terms of binding ability to Ramos cells (Figure 3A) and agonistic activity (Figure 3B). The fluctuation in activity due to introduction of the P331S variation was not observed.

Example 9: Measurement of CDC activity of anti-CD40 agonistic antibody 331ser mutant

CDC activity was measured by the above method. A rabbit serum-derived complement was used, and Ramos cells were used as target cells. The results confirmed that, in a KM341-1-19 antibody at an antibody concentration of 1 µg/ml, IgG2ser exhibited CDC activity significantly reduced as compared with IgG2 (Figure 4A). On the other hand, when a human supplement was used, no change was observed (Figure 4B).

Example 10: Preparation and activity measurement of agonist anti-CD40 antibody having constant region converted

Among the anti-CD antibodies described in WO 02/088186, two antibodies exhibiting strongest agonistic activity (KM341-1-19 antibody and 2105 antibody) belong to IgG2 subclass. In order to examine whether or not the IgG2 subclass is important for activation of CD40, recombinant proteins having an antibody constant region converted into IgG1, IgG3 and IgG4, respectively, were prepared, and measured in terms of binding ability to an antigen and CD95 expression enhancing activity in Ramos cells according to Examples 4 and 6. IgG1 was expressed using N5KG1, and IgG2 and IgG3 were respectively expressed using expression vectors N5KG2 and N5KG3 obtained by substituting the N5KG1 constant region

with IgG2 and IgG3, respectively. cDNA cloning of the IgG3 constant region was carried out according to the IgG2 cloning method partially modified, using an IgG3-specific primer. IgG4 was expressed using N5KG4PE (IDEC Pharmaceuticals).

The antibody protein was expressed according to Example 1. Binding activity to Ramos cells expressing human CD40 of the KM341-1-19 antibody and the 2105 antibody was not affected by converting IgG2 into IgG1, IgG3 or IgG4 (Figures 5A-1 and 5A-2). However, these antibodies were found to have CD95 expression enhancing activity in Ramos cells reduced by 10% or more (Figures 5B-1 and 5B-2). This shows that not only the structure of the variable region defining the binding region of the antibody but also the structure of the constant region of the antibody are important for the strong agonistic activity of the 2105 antibody and the KM341-1-19 antibody. Thus, in order to examine which region in the IgG2 constant region is important for agonistic activity, a domain swap mutant in which the IgG2 structure is mixed with the IgG4 structure was prepared to measure its activity. As described below, a domain swap mutant is prepared by substitution of a hinge region. In this case, the "hinge region" includes the upper hinge (from Kabat EU code 216), middle hinge (from Kabat EU code 226) and lower hinge (Kabat EU code 231), as described Ole H Brekke et. al., Immunology Today 1995, 16, 85-90. Four domain swap mutants IgG2/4 (CH1 and hinge region: IgG2, other regions: IgG4), IgG4/2/4 (hinge region: IgG2, other regions: IgG4), IgG2/4/4 (CH1: IgG2, other regions: IgG4) and IgG4/2/2 (CH1: IgG4, other regions: IgG2) were prepared respectively for the KM341-1-19 antibody and the 2105 antibody.

A vector N5KG2/4 for expressing the IgG2/4 antibody was prepared using a Ztaq PCR kit (Takara). Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers IgG3Bam: atatgatccTCATTTACCCGGAGACAGGGAGAGGC (SEQ ID NO: 8) and 24Chi4: AGGGGTCCGGGAGATCATGAGAGTGTCCTT (SEQ ID NO: 9). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG4 (IDEC Pharmaceuticals) as a template and primers 24Chi3: AAGGACACTCTCATGATCTCCCGGACCCCT (SEQ ID NO: 10) and linkH2: tgatcatacgtagatatcacggc (SEQ ID NO: 11). The amplified DNA fragments were purified

using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers IgG3Bam and linkH2: tgatcatcacgtagatatcacggc (SEQ ID NO: 12) were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector.

A vector N5KG4/2/4 for expressing IgG4/2/4 was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG4 as a template and primers linkH: gggtacgtcctcacattcagtgatcag (SEQ ID NO: 13), G2Hin3: TTTGCGCTCAACTGTCTTGTCCACCTTGGTGTGCTGGG (SEQ ID NO: 14), linkH2: tgatcatcacgtagatatcacggc (SEQ ID NO: 15) and G2Hin4: ACAGTTGAGCGCAAATGTTGTGTCGAGTGCCACCG (SEQ ID NO: 16). The amplified DNA fragments were purified with a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times using the mixture as a template. Primers linkH and linkH2 were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector.

A vector N5KG2/4/4 for expressing IgG2/4/4 was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers linkH: gggtacgtcctcacattcagtgatcag (SEQ ID NO: 17) and G4CH1-2: GGTGTTGCTGGGCTTGTGATCTACGTTGCAG (SEQ ID NO: 18). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG4 as a template and primers G4CH1-1: CTGCAACGTAGATCACAAGCCCAGCAACACC (SEQ ID NO: 19) and linkH2: tgatcatcacgtagatatcacggc (SEQ ID NO: 20). The amplified DNA fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers linkH and linkH2 were added to the mixture, and

the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with *NheI* and *BamHI*, and substituted with the IgG1 constant region of the N5KG1 vector.

A vector N5KG4/2/2 for expressing IgG4/2/2 was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out using N5KG4 as a template and primers linkH: gggtagctcctcacattcagtgatcag (SEQ ID NO: 21) and G4CH1-2: GGTGTTGCTGGGCTTGTGATCTACGTTGCAG (SEQ ID NO: 22). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers G4CH1-1: CTGCAACGTAGATCACAAGCCCAGCAACACC (SEQ ID NO: 23) and linkH2: tgatcatagctagatatcacggc (SEQ ID NO: 24). The amplified DNA fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers linkH and linkH2 were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with *NheI* and *BamHI*, and substituted with the IgG1 constant region of the N5KG1 vector.

Binding activity of the respective four domain swap mutants of the KM341-1-19 antibody and the 2105 antibody was examined. As a result, no difference between them and the original IgG2 was observed in terms of binding ability (Figures 6A-1 and 6A-2). However, only IgG2/4/4 of both the KM341-1-19 antibody and the 2105 antibody exhibited significantly reduced agonistic activity (Figures 6B-1 and 6B-2). The results confirmed that the hinge region of IgG2 is important for agonistic activity.

Further, it was examined which sequence is important in the hinge region. The hinge region is divided into three sites, specifically, upper hinge, middle hinge and lower hinge (Ole H Brekke et al. Immunology Today 1995, 16, 85-90). IgG2-specific sequences in these regions were respectively substituted with IgG4-specific sequences. Antibodies obtained by introducing a mutation into the upper hinge (from Kabat EU code 216), middle hinge (from Kabat EU code 226) and lower hinge (from Kabat EU code 231) were respectively defined as IgG2UH4, IgG2MH4 and IgG2LH4. Their respective expression vectors were defined as

N5KG2UH4, N5KG2MH4 and N5KG2LH4. "Hinge" is defined as EU indices 216 to 230 according to Kabat et al., Sequences of proteins of immunological interest, 1991 Fifth edition.

N5KG2UH4 was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers linkH: gggtagctcctcacattcagtgatcag (SEQ ID NO: 25) and UH4-2: CACAACATTTggaCTCAACTcTCTTGTCACC (SEQ ID NO: 26). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers UH4-1: GGTGGACAAGAgAGTTGAGtccAAATGTTGTG (SEQ ID NO: 27) and linkH2: tgatcatagtagatatcacggc (SEQ ID NO: 28). The amplified DNA fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers linkH and linkH2 were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector.

N5KG2MH4 was prepared as follows. Reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers linkH: gggtagctcctcacattcagtgatcag (SEQ ID NO: 29) and UM4-2: GGCACGGTGGGCAatgggggaccataTTTGCGCTC (SEQ ID NO: 30). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers UM4-1: GAGCGCAAAtatggtccccaTGCCCACCGTGCC (SEQ ID NO: 31) and linkH2: tgatcatagtagatatcacggc (SEQ ID NO: 32). The amplified DNA fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers linkH and linkH2 were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector.

N5KG2LH4 was prepared as follows. Reaction at 98°C for 4 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers linkH: gggtacgtcctcacattcagtgatcag (SEQ ID NO: 33) and UL4-2: GAAGACTGACGGTCCccccaggaactcTGGTGCTGGGCA (SEQ ID NO: 34). At the same time, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out 15 times using N5KG2 as a template and primers UL4-1: TGCCCAGCACCAgagttcctggggGGACCGTCAGTCTTC (SEQ ID NO: 35) and linkH2: tgatcatagtagatatcacggc (SEQ ID NO: 36). The amplified DNA fragments were purified using a PCR purification kit, and the same amounts of the two purified DNA fragments were mixed. Thereafter, reaction at 98°C for 1 second, at 60°C for 30 seconds and at 72°C for 30 seconds was carried out five times. Primers linkH and linkH2 were added to the mixture, and the same reaction was carried out 15 times. The amplified DNA fragment was cleaved with NheI and BamHI, and substituted with the IgG1 constant region of the N5KG1 vector.

The three respective domain swap mutants of the KM341-1-19 antibody and the 2105 antibody were examined to have the same binding activity to an antigen (Figures 6A-1 and 6A-2). However, IgG2UH4 and IgG2MH4 exhibited significantly reduced agonistic activity to Ramos cells (Figures 6B-1 and 6B-2). It was found from the above that the structures of upper hinge and middle hinge in the hinge region are important for IgG2 subclass-dependent agonistic activity of the anti-CD40 antibodies KM341-1-19 and 2105.

Since IgG2 subclass was found to be important for agonistic activity, antibodies of subclass other than IgG2 were converted to those of IgG2 subclass to examine whether or not the agonistic activity was enhanced. In the examination on several clones, agonistic activity of F76 could be enhanced by converting IgG1 subclass to IgG2 subclass (Figures 7A and B).

Example 11: Preparation of anti-CD40 antagonist antibody mutants

A DNA fragment containing a heavy chain and a light chain of a 4D11 antibody gene described in WO 02/088186, whose original subclass is IgG1, was digested with BglII and NheI, purified, and then integrated into N5KG4PE, N5KG4P and N5KG4 vectors (IDEC Pharmaceuticals). N5KG4PE contains point mutations S228P and L235E in the IgG4

constant region, and N5KG4P contains a point mutation S228P in the IgG4 constant region. The antibody protein was expressed and purified according to the above method. The antibody was purified according to the above method using binding to Ramos cells as an index. Change in binding activity of IgG1, IgG4, IgG4P and IgG4PE to Ramos cells was not observed (Figure 8A). Antagonistic activity of IgG1 was compared with those of various IgG4 mutants according to the above method to find that antagonistic activity of IgG1 does not differ from those of the IgG4 mutants (Figure 8B).

Example 12: Evaluation of ADCC activity and CDC activity of anti-CD40 antagonist antibody mutants

ADCC activity and CDC activity of anti-CD40 mutant antibodies were evaluated according to the above method.

When using human MNC as effector cells and CD40-expressing Daudi cells as target cells, two mutants IgG4 and IgG4PE were respectively observed to have ADCC activity significantly reduced as compared with IgG1 as the original subclass of the 4D11 antibody (Figure 9).

CDC activity of IgG1 was compared with that of IgG4P using Daudi cells as target cells. IgG4P was found to have CDC activity significantly reduced as compared with IgG1 (Figure 10).

Example 13: Effect of anti-CD40 antagonistic antibody on B cells

100 µg each of IgG1, IgG4P and IgG4PE of the 4D11 antibody was administered to the tail vein of mice having a genetic background whereby they were homozygotes for mouse endogenous disrupted CD40 and harboring a transgene of a human CD40 gene (Yasui. et al. Int. Immunol. 2002 Vol 14: 319). 24 hours after the administration, blood was collected from the orbital venous plexus. After hemolysis with 0.16 mol/L of ammonium chloride, an FITC-labeled anti-B220 antibody was added to the hemolysate, and it was analyzed using FACS. The results are shown in Figure 11. In the figure, the longitudinal axis indicates the ratio of B cells in the total lymphocytes. IgG1 reduced the ratio of B cells most, IgG4P

reduced the ratio to a lesser extent, and IgG4PE reduced the ratio to a much lesser extent. 24 hours after the administration, the spleen was removed and crushed with a slide glass to prepare a cell suspension. After hemolysis of the cell suspension, a PE-labeled anti-B220 antibody and an FITC-labeled anti-CD23, CD86 or CD95 antibody were used for the hemolysate, and it was analyzed using FACS. The results are shown in Figures 12A, B and C. In the figures, the longitudinal axis indicates the ratio of B cells expressing each surface marker in the total lymphocytes. 4D11G1 was found to achieve the same level of increase in expression of each marker as in a commercially available mouse anti-human CD40 agonistic antibody 5C3 (Pharmingen). IgG4PE achieved a smaller increase in expression of each activation surface marker as compared with IgG1 and IgG4P.

Example 14: Effect of inhibiting production of antigen-specific antibody and change in the number of B cells caused by anti-CD40 antagonistic antibody

100 µg (based on NP-CGG) of a complex of 4-hydroxy-3-nitrophenylacetyl-chicken γ-globulin conjugates (NP-CGG: distributed by Professor Hitoshi KIKUTANI, Research Institute for Microbial Diseases, Osaka University) and alum (aluminum hydroxide gel) was intraperitoneally administered to mice having a genetic background whereby they were homozygotes for mouse endogenous disrupted CD40 and harboring a transgene of a human CD40 gene (Yasui et al. Int. Immunol. 2002 Vol 14: 319) to sensitize the mice. Immediately before the antigen sensitization, 50 or 100 µg of each antibody was administered to the tail vein. 100 µg of an anti-human albumin human IgG4PE antibody was administered as a negative control. 7 and 14 days after the sensitization, blood was collected from the orbital venous plexus. The amounts of NP-specific IgG1 and IgM antibodies in the serum were measured by the ELISA method. The ELISA method was carried out as follows. 50 µl/well of NP-bound bovine serum albumin (NP-BSA: 2.5 µg/ml) was added to each well of a 96-well microplate for ELISA (Maxisorp, manufactured by Nunc A/S) and incubated at 4°C to cause NP-BSA to be adsorbed thereon. Next, the supernatant was discarded, and a blocking reagent (SuperBlock, manufactured by Pierce Biotechnology, Inc.) was added to each well and incubated at room temperature to carry out blocking. Then, each well was washed with a

phosphate buffer (PBS-T) containing 0.1% Tween 20 three times. Next, each serum diluted with PBS-T containing 10% Block Ace (50 μ l/well) was added to each well, and incubated and reacted at 37°C for two hours. The microplate was washed with PBS-T three times. Then, a 1,000-fold dilution of a goat anti-mouse IgG1 antibody or IgM antibody labeled with alkaline phosphatase (Cosmo Bio, 1070-04 or 1020-04) with PBS-T containing 10% Block Ace (50 μ g/well) was added to each well, and incubated at 37°C for two hours. Next, the microplate was washed with PBS-T, and then a coloring substrate solution (50 μ l/well, Sigma 104, phosphatase substrate) was added to each well. The absorbance at a wavelength of 405 nm was measured using a microplate reader. The results are shown in Figures 13A and B. In the figures, the longitudinal axis indicates values obtained by converting a 10,000-fold dilution (in the case of IgG1) or 100-fold dilution (in the case of the IgM antibody) of serum collected from C57BL/6 mice, to which NP-CGG was injected twice, and pooled into one unit. The 4D11 antibody and the IgG4P or IgG4PE antibody of 281 inhibited production of NP-specific IgG1 and IgM antibodies equally strongly.

The change in the number of B cells in the peripheral blood and spleen in the mice used for examining the effect of inhibiting antibody production was measured according to the same method as in Example 1. The results are shown in Figures 14A and B. The 4D11 antibody and the IgG4P antibody of 281 reduced the ratio of B cells in peripheral blood significantly as compared with the IgG4PE antibody. Administration of 100 μ g of the IgG4PE antibody did not change the ratio of B cells in the spleen removed 14 days after the antigen sensitization. However, administration of IgG4P changed or tended to change the ratio.

Example 15: Effect of anti-CD40 antagonistic antibody on cynomolgus monkeys

30 mg/kg of IgG4P or IgG4PE of a 4D11 antibody was administered to the forearm cephalic vein of cynomolgus monkeys, and blood was collected from the femoral vein after a certain period of time. In the subset analysis of peripheral blood lymphocytes, an FITC-labeled anti-CD3 antibody, PE-labeled anti-CD20 antibody and APC-labeled anti-CD45 antibody were used for each cell suspension, and the ratio of positive cells was measured using

FACS to calculate the ratio of CD45 positive cells. The results are shown in Figure 15. In the figure, the longitudinal axis indicates the ratio of CD20 positive cells at each time to CD20 positive cells before antibody administration. 1 to 7 days after the antibody administration, CD20 positive cells were reduced by about 40% in individuals to which the IgG4P antibody was administered. However, 4 days after the administration, CD20 positive cells were reduced by only about 20% in individuals to which the IgG4PE antibody was administered.

The IL12 concentration in serum was measured by the ELISA method. Blood collected from the femoral vein was allowed to stand at room temperature for 20 to 60 minutes, and then centrifuged at 3,000 rpm at room temperature for 15 minutes. The IL12 concentration in the resulting serum was measured using a monkey IL12 ELISA kit (BioSource International Inc.). The results are shown in Figure 16. No increase in IL12 production by the IgG4PE antibody was observed at any blood collection point. However, maximum IL12 production by the IgG4P antibody was observed on the 4th day.

Example 16: Effect of anti-CD40 antagonistic antibody on cynomolgus monkey delayed hypersensitivity model

Nine male cynomolgus monkeys were intradermally and intramuscularly sensitized with Tetanus toxoid (TTx) (10 Lf/ml; Denka Seiken Co., Ltd.) to induce delayed hypersensitivity to TTx. At the same time, 10 minutes before the start of sensitization, 0.1 and 10 mg/kg of a 4D11G4PE antibody was intravenously administered to each three animals three times (once a week) to examine the effect of 4D11G4PE on delayed hypersensitivity. Under anesthesia by intramuscular administration of ketamine, sensitization was carried out by intradermal administration of TTx to the back ($50 \mu\text{L}/\text{site} \times 12 \text{ sites}$) and intramuscular administration of TTx to the femur (0.6 mL/body), and challenge was carried out by intradermal administration of TTx to the thorax ($10 \mu\text{L}/\text{site}$, 0 to 10 Lf/ml for each three sites) 21 days after the sensitization. 24 and 48 hours after the elicitation, skin reaction at the administration sites was observed and evaluated according to the Draize skin irritation score. The results of determining the TTx concentration in each three sites were respectively a mean value. The results are shown in Figure 17. Administration of the 4D11G4PE antibody

apparently inhibited the delayed hypersensitivity reaction observed 24 and 48 hours after the administration.

The effect of TTx on TTx-specific IgG and IgM antibody titers was examined. Blood collected from the femoral vein over time was allowed to stand at room temperature for 20 to 60 minutes, and then centrifuged at 3,000 rpm at room temperature for 15 minutes. The antibody titer in the resulting serum was measured using the ELISA method. The ELISA method was carried out as follows. 100 μ l/well of TTx (0.5 Lf/ml) was added to each well of a 96-well microplate for ELISA (Maxisorp, manufactured by Nunc A/S) and incubated at 4°C to cause TTx to be adsorbed thereon. Next, the supernatant was discarded, and a blocking reagent (phosphate buffer containing 0.5% BSA) was added to each well and incubated at room temperature to carry out blocking. Then, each well was washed with a phosphate buffer (PBS-T) containing 0.05% Tween 20 three times. Next, each serum diluted with PBS-T containing 0.5% BSA (100 to 819,200-fold dilution, dilution magnification: 2; 100 μ l/well) was added to each well, and incubated and reacted at room temperature for two hours. The microplate was washed with PBS-T three times. Then, a 3,000-fold dilution of a goat anti-monkey IgG antibody or IgM antibody labeled with peroxidase (Nordic Immunology) with PBS-T containing 0.5% BSA (100 μ g/well) was added to each well, and incubated at room temperature for one hour. Next, the microplate was washed with PBS-T, and then a coloring substrate solution (100 μ l/well, o-phenylenediamine hydrochloride + aqueous hydrogen peroxide) was added to each well. The absorbance at a wavelength of 492 nm was measured using a microplate reader. The anti-TTx antibody titer was defined as a maximum dilution magnification to make the absorbance 0.1 and more. The antibody titer was 0 when the absorbance did not reach 0.1 even at 100-fold dilution. The results are shown in Figures 18 and 19. Administration of 1 mg/kg of 4D11G4PE suppressed the TTx-specific IgG and IgM antibody titers to about 1/10. When 10 mg/kg of 4D11G4PE was administered, the antibody titers were below the detection sensitivity at any blood collection point.

Example 17: Effect of anti-CD40 antagonistic antibody on platelet thrombus formation

Blood collected from a healthy human was divided into four aliquots (each 6 ml). Control human IgG4PE, control mouse IgG2a, human anti-human CD40 IgG4PE (4D11) and mouse anti-human CD154 IgG2a (5C8) were respectively added to the fractions so that each fraction had a blood concentration of 100 µg/ml. A flat perfusion chamber (GlycoTech Corp.) and a collagen-coated Petri dish were assembled according to the attached instruction. The blood treated with various antibodies was caused to flow into the chamber at a rate that can apply a shear stress of 1,500/s to the blood for seven minutes. Thereafter, a 4% paraformaldehyde phosphate buffer was caused to flow into the chamber at a rate that can apply a shear stress of 1,500/s to the buffer for 10 minutes. The platelet aggregate formed on the Petri dish was fixed, stained with a platelet-specific PE-labeled CD41a antibody, and observed with a fluorescence microscope. The results are shown in Figures 20A and B. The blood treated with human anti-human CD40 IgG4PE (4D11) formed a platelet aggregate on the collagen-coated Petri dish, as the blood treated with the control antibodies did. However, the blood treated with mouse anti-human CD154 IgG2a did not form a platelet aggregate.

Example 18: Evaluation of stability of anti-CD40 antagonistic antibody

Constant region-modified antibodies of the 4D11 antibody were compared and examined in terms of stability. In the evaluation method, culture supernatants obtained by respectively transiently expressing G4P, G4PE, G2Ser and G4/2/4 in HEK293 cells were charged with a Protein A column (Amersham Pharmacia Biotech), eluted with a 0.1 M citrate buffer (pH 2.7), and then incubated at 37°C for 1 minute and 10 minutes. Thereafter, they are neutralized with a 50 nM phosphate buffer (pH 7.0). The oligomer content in the resulting antibody solutions was measured using a gel filtration column (Tosoh Corp.). As a result, it was found that the oligomer content increases in proportion with the incubation time, and G4/2/4 produces an oligomer easiest, G4PE second easiest, G2Ser third easiest, and G4P fourth easiest (Figure 21).

Example 19: Effect of inhibiting skin graft rejection by anti-CD40 antagonistic antibody

A graft collected from the tail of DBA/2 mice was grafted into the side dorsal thorax of C57BL/6 background mice having a genetic background whereby they were homozygotes for mouse endogenous disrupted CD40 and harboring a transgene of a human CD40 gene, and the graft was fixed with a plaster for seven days. 100 µg of a test substance 4D11G4PE or a vehicle was administered to the tail vein 0, 2, 4, 7, 9, 11 and 14 days after the skin graft, respectively. To inhibit graft rejection by NK cells, 100 µg of an anti-asialo GML antibody was intraperitoneally administered to all mice 3 days before the operation and 1, 4 and 9 days after the operation. The results are shown in Figure 22. The delay in graft rejection was observed to be significant in the 4D11G4PE-administered group as compared with the vehicle-administered group.

Example 20: Analysis of CD40 expression in human tumor cell lines

Expression of CD40 in a Burkitt's lymphoma cell line Ramos, bladder cancer cell line T24 (ATCC, HTB-4), pancreatic cancer cell line Hs 766T (ATCC, HTB-134) and Capan-2 (ATCC, HTB-80) was confirmed by FACS analysis using 341G2Ser.

T24, Hs 766T and Capan-2 were digested with trypsin and harvested, and Ramos was harvested as is. The cell lines were washed with PBS, and then re-suspended in a staining buffer containing 1 µg/ml of 341G2Ser. The staining buffer was prepared by adding 0.05 mM EDTA, 0.05% sodium azide and 5% immobilized bovine serum to PBS. After incubation at 4°C for 15 minutes, the cells were washed with the staining buffer twice, and re-suspended in a 1:250 dilution of PE-bound goat anti-human IgG (γ) (Southern Biotechnology Associates, Inc) with the staining buffer. After incubation at 4°C for 15 minutes, the cells were washed with the staining buffer twice, and analyzed with FACSCalibur (manufactured by BD Biosciences). The same amount of a human anti-2,4-dinitrophenol (DNP) antibody was used as a negative control. The analysis was carried out using Cellquest (manufactured by BD Biosciences) as data analysis software to calculate the mean fluorescence intensity.

As a result, Ramos, T24, Hs766T and Capan-2 had a mean fluorescence intensity obviously higher than that of the negative control when stained with 341G2Ser, and thus expression of CD40 was confirmed.

Example 21: Effect of anti-CD40 agonistic antibody on human tumor cell lines

2.5×10^3 Ramos cells, 2.5×10^2 T24 cells, 5×10^3 Hs766T cells and 5×10^3 Capan-2 cells were respectively suspended in a medium to make the total volume of 100 μ L in a flat bottom 96-well plate (manufactured by Falcon). Ramos and Hs766T, Capan-2 and T24 were cultured for 66 hours, 90 hours and 114 hours, respectively, together with 341G2Ser at a concentration of 1 ng/ml to 1,000 ng/ml at 37°C in the presence of 5% CO₂. 10 μ L (3.7 MBq/mL) of ³H-labeled thymidine (manufactured by Amersham Biosciences) was added and cultured at 37°C in the presence of 5% CO₂ for six hours. Ramos cells were harvested on Printed Filtermat A (manufactured by PerkinElmer, Inc.) using a 96 micro cell harvester (manufactured by Skatron Instruments, Inc.), and covered with a sample bag (manufactured by PerkinElmer, Inc.). 12 mL of Betaplate Scint (manufactured by PerkinElmer, Inc.) was added, and the β -ray dose was measured with a liquid scintillation counter (Pharmacia 1205 Betaplate: manufactured by Pharmacia Corp.). Hs 766T cells, T24 cells and Capan-2 cells were respectively harvested on Unifilter (manufactured by PerkinElmer, Inc.) using a harvester (manufactured by PerkinElmer, Inc.). A special seal was attached to the back of each filter, and 20 μ L/well of MicroScint 20 (manufactured by PerkinElmer, Inc.) was added thereto. The β -ray dose was measured with a scintillation counter (TopCount: manufactured by Packard Instrument Co., Inc.). Data were expressed as cell survival rates (%) obtained by dividing a mean of triplicate measurements obtained in three independent tests by a value of non-treatment control.

As a result, the cell survival rates were reduced in all cell lines depending on the 341G2Ser concentration (Table 1). When adding 100 ng/ml of 341G2Ser, the Ramos cell survival rate was 58%, the T24 cell survival rate was 22%, the Hs 766T cell survival rate was 15%, and the Capan-2 cell survival rate was 77%. 341G2Ser was found to have activity of inhibiting growth of Ramos cells, T24 cells, Hs 766T cells and Capan-2 cells.

Table 1

Cell line	341G2Ser concentration (ng/ml)			
	1	10	100	1000
Ramos	98.49%	81.68%	57.77%	55.26%
T24	97.94%	50.72%	21.97%	25.35%
Hs 766T	34.67%	21.50%	14.67%	15.18%
Capan-2	100.94%	85.34%	76.76%	72.89%

Example 22: Effect of anti-CD40 agonistic antibody on mouse cancer-bearing model

(1) Ramos cells

Six-week-old female Balb/c nude mice (purchased from CLEA Japan, Inc.) were irradiated with 3Gy radiation, and 2×10^7 cells/mouse of Ramos cells were subcutaneously grafted into the back thereof. 16 days after the graft, the size of tumors that took there was measured. Cancer-bearing mice having a tumor size of 50 to 170 mm³ were classified into groups each consisting of five mice. 100 µg/mouse of 341G2Ser (a solution in 200 µl of PBS containing 1% nude mouse serum) was intravenously administered to the cancer-bearing mice once on the 16th day, and the tumor size was measured until the 47th day. A human anti-human serum albumin (HAS) antibody was used as a negative control.

(2) T24 cells

A T24 cell mass that had undergone subcutaneous passage in the back of nude mice three times were removed, and subcutaneously grafted into the back of six-week-old female Balb/c nude mice (purchased from CLEA Japan, Inc.). The tumor cell mass to be grafted is appropriately about 3 mm square. 10 days after the graft, the size of engrafted tumors was measured. Cancer-bearing mice having a tumor size of 80 to 200 mm³ were classified into groups each consisting of five mice. 100 µg/mouse of 341G2Ser (a solution in 200 µl of PBS containing 1% nude mouse serum) was intravenously administered to the cancer-bearing mice once on the 10th day, and the tumor size was measured until the 29th day. The same amount of a human anti-DNP antibody was used as a negative control.

(3) Hs 766T cells

7×10^5 cells/mouse of Hs 766T cells were subcutaneously grafted into the back of eight-week-old female Balb/c nude mice (purchased from CLEA Japan, Inc.). 16 days after the graft, the size of engrafted tumors was measured. Cancer-bearing mice having a tumor size of 50 to 140 mm³ were classified into groups each consisting of five mice. 100 µg/mouse of 341G2Ser (a solution in 200 µl of PBS containing 1% nude mouse serum) was intravenously administered to the cancer-bearing mice once on the 16th day, and the tumor size was measured until the 32nd day. The same amount of a human anti-DNP antibody was used as a negative control.

(4) Capan-2 cells

2×10^6 cells/mouse of Capan-2 cells were subcutaneously grafted into the back of six-week-old female Balb/c nude mice (purchased from CLEA Japan, Inc.). 13 days after the graft, the size of engrafted tumors was measured. Cancer-bearing mice having a tumor size of 30 to 130 mm³ were classified into groups each consisting of five mice. 10 or 100 µg/mouse of 341G2Ser (a solution in 200 µl of PBS containing 1% nude mouse serum) was intravenously administered to the cancer-bearing mice twice a week from the 13th day, and the tumor size was measured until the 34th day. A human polyclonal antibody (hIgG) (manufactured by Sigma Co.) was used as a negative control.

The tumor growth inhibition ratio (TGIR) was calculated from the following formula.
$$100 - \left\{ \frac{(\text{mean tumor volume of 341G2Ser-administered group on the last measurement day} - \text{mean tumor volume of 341G2Ser-administered group on the day of start of antibody administration})}{(\text{mean tumor volume of negative control-administered group on the last measurement day} - \text{mean tumor volume of negative control-administered group on the day of start of antibody administration})} \right\} \times 100$$

As a result, TGIR exceeded 100% in the T24, Hs766T and Capan-2 cancer-bearing mice, and a decrease in the tumor volume was observed in the mice. On the other hand, TGIR was 73.4% in the Ramos cancer-bearing mice, and an increase in the tumor volume was considerably suppressed in the mice (Table 2). Figures 23 to 26 respectively show the

change in the tumor volume of cancer-bearing mice to which Ramos cells, T24 cells, Hs 766T cells and Capan-2 cells were respectively engrafted.

Table 2

Cell line	Amount of 341G2Ser administered	
	10 µg/head	100 µg/head
Ramos	-	73.40%
T24	-	109.05%
Hs 766T	-	108.55%
Capan-2	103.49%	119.20%

The inhibition ratio in each cell line is a value on the last measurement day.

Industrial Applicability

As shown in the Examples, the anti-CD40 antibody of the present invention having a constant region into which a mutation is introduced and an anti-CD40 antibody in which a part of the structure of the subclass is substituted with that of another subclass have reduced ADCC activity and CDC activity, while maintaining its activity. Accordingly, the antibody of the present invention has the reduced cytotoxicity to CD40-expressing cells when administered to a subject as a therapeutic antibody, and thus can be used with safety.
